Description

The routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices *A* and *B*. On entry, it is assumed that matrices *A* and *B* have the following forms, which may be obtained by the preprocessing subroutine [ggsvp](#) from a general *m*-by-*n* matrix *A* and *p*-by-*n* matrix *B*:

$$A = \begin{matrix} & n-k-l & k & l \\ \begin{matrix} k \\ l \\ m-k-l \end{matrix} & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}, \quad \text{if } m-k-l \geq 0$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal.

On exit,

$$U^{H*}A^*Q = D_1^*(0, R), \quad V^{H*}B^*Q = D_2^*(0, R),$$

where U , V and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 and D_2 are "diagonal" matrices, which are of the following structures:

If $m-k-1 \geq 0$,

$$D_1 = \begin{matrix} & k & l \\ \begin{matrix} k \\ l \\ m-k-l \end{matrix} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$D_t = \begin{matrix} & k & l \\ p-1 & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} n-k-l & k & l \\ k & R_{11} & R_{12} \\ l & 0 & R_{22} \end{matrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+1))$$
$$S = \text{diag}(\text{beta}(k+1), \dots, \text{beta}(k+1))$$
$$C^2 + S^2 = I$$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-1 < 0$,

$$\begin{array}{ccc} & k & m-k & k+1-m \\ \begin{array}{c} k \\ m-k \end{array} & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{array}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ \begin{matrix} m-k \\ k+l-m \\ p-l \end{matrix} & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

0111 010001 00000000 00000000 00000000 00000000 00000000 00000000

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(m)),$$
$$S = \text{diag}(\text{beta}(k+1), \dots, \text{beta}(m)),$$
$$C^2 + S^2 = I$$

On exit, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ \mathbf{0} & R_{22} & R_{23} \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The computation of the orthogonal/unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they *may* be postmultiplied into input matrices U_1 , V_1 , or Q_1 .

Input Parameters

<i>jobu</i>	<p>CHARACTER*1. Must be 'U', 'I', or 'N'.</p> <p>If <i>jobu</i> = 'U', <i>u</i> must contain an orthogonal/unitary matrix U_1 on entry.</p> <p>If <i>jobu</i> = 'I', <i>u</i> is initialized to the unit matrix.</p> <p>If <i>jobu</i> = 'N', <i>u</i> is not computed.</p>
<i>jobv</i>	<p>CHARACTER*1. Must be 'V', 'I', or 'N'.</p> <p>If <i>jobv</i> = 'V', <i>v</i> must contain an orthogonal/unitary matrix V_1 on entry.</p> <p>If <i>jobv</i> = 'I', <i>v</i> is initialized to the unit matrix.</p> <p>If <i>jobv</i> = 'N', <i>v</i> is not computed.</p>
<i>jobq</i>	<p>CHARACTER*1. Must be 'Q', 'I', or 'N'.</p> <p>If <i>jobq</i> = 'Q', <i>q</i> must contain an orthogonal/unitary matrix Q_1 on entry.</p> <p>If <i>jobq</i> = 'I', <i>q</i> is initialized to the unit matrix.</p> <p>If <i>jobq</i> = 'N', <i>q</i> is not computed.</p>
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix B ($p \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
<i>k, l</i>	INTEGER. Specify the subblocks in the input matrices A and B , whose GSVD is computed.
<i>a, b, u, v, q, work</i>	<p>REAL for stgsja</p> <p>DOUBLE PRECISION for dtgsja</p> <p>COMPLEX for ctgsja</p> <p>DOUBLE COMPLEX for ztgsja.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> contains the m-by-n matrix A.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b(ldb,*)</i> contains the p-by-n matrix B.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p>If <i>jobu</i> = 'U', <i>u(ldu,*)</i> must contain a matrix U_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).</p> <p>The second dimension of <i>u</i> must be at least $\max(1, m)$.</p> <p>If <i>jobv</i> = 'V', <i>v(ldv,*)</i> must contain a matrix V_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).</p> <p>The second dimension of <i>v</i> must be at least $\max(1, p)$.</p>

If $jobq = 'Q'$, $q(ldq,*)$ must contain a matrix Q_1 (usually the orthogonal/unitary matrix returned by `?ggsvp`).

The second dimension of q must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, 2n)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, p)$.

ldu INTEGER. The leading dimension of the array u .
 $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.

ldv INTEGER. The leading dimension of the array v .
 $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.

ldq INTEGER. The leading dimension of the array q .
 $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.

$tola, tol b$ REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

$tola$ and $tol b$ are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in `?ggsvp`:

$tola = \max(m, n) * |A| * \text{MACHEPS}$,

$tol b = \max(p, n) * |B| * \text{MACHEPS}$.

Output Parameters

a On exit, $a(n-k+1:n, 1:\min(k+l, m))$ contains the triangular matrix R or part of R .

b On exit, if necessary, $b(m-k+1:l, n+m-k-l+1:n)$ contains a part of R .

$alpha, beta$ REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays, size at least $\max(1, n)$. Contain the generalized singular value pairs of A and B :

$alpha(1:k) = 1$,

$beta(1:k) = 0$,

and if $m-k-l \geq 0$,

$alpha(k+1:k+l) = \text{diag}(C)$,

$beta(k+1:k+l) = \text{diag}(S)$,

or if $m-k-l < 0$,

$alpha(k+1:m) = \text{diag}(C)$, $alpha(m+1:k+l) = 0$

$beta(k+1:m) = \text{diag}(S)$,

$\beta(m+1:k+1) = 1.$

Furthermore, if $k+1 < n$,

$\alpha(k+1+1:n) = 0$ and

$\beta(k+1+1:n) = 0.$

u If *jobu* = 'I', *u* contains the orthogonal/unitary matrix *U*.
 If *jobu* = 'U', *u* contains the product U_1^*U .
 If *jobu* = 'N', *u* is not referenced.

v If *jobv* = 'I', *v* contains the orthogonal/unitary matrix *U*.
 If *jobv* = 'V', *v* contains the product V_1^*V .
 If *jobv* = 'N', *v* is not referenced.

q If *jobq* = 'I', *q* contains the orthogonal/unitary matrix *U*.
 If *jobq* = 'Q', *q* contains the product Q_1^*Q .
 If *jobq* = 'N', *q* is not referenced.

ncycle INTEGER. The number of cycles required for convergence.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = 1, the procedure does not converge after MAXIT cycles.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `tgsja` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m,n) .
<i>b</i>	Holds the matrix <i>B</i> of size (p,n) .
<i>u</i>	Holds the matrix <i>U</i> of size (m,m) .
<i>v</i>	Holds the matrix <i>V</i> of size (p,p) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n,n) .
<i>alpha</i>	Holds the vector of length <i>n</i> .
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>jobu</i>	If omitted, this argument is restored based on the presence of argument <i>u</i> as follows: $jobu = 'U'$, if <i>u</i> is present, $jobu = 'N'$, if <i>u</i> is omitted.

If present, *jobu* must be equal to 'I' or 'U' and the argument *u* must also be present.

Note that there will be an error condition if *jobu* is present and *u* omitted.

jobv

If omitted, this argument is restored based on the presence of argument *v* as follows:

jobv = 'V', if *v* is present,

jobv = 'N', if *v* is omitted.

If present, *jobv* must be equal to 'I' or 'V' and the argument *v* must also be present.

Note that there will be an error condition if *jobv* is present and *v* omitted.

jobq

If omitted, this argument is restored based on the presence of argument *q* as follows:

jobq = 'Q', if *q* is present,

jobq = 'N', if *q* is omitted.

If present, *jobq* must be equal to 'I' or 'Q' and the argument *q* must also be present.

Note that there will be an error condition if *jobq* is present and *q* omitted.

Cosine-Sine Decomposition

This section describes LAPACK computational routines for computing the *cosine-sine decomposition* (CS decomposition) of a partitioned unitary/orthogonal matrix. The algorithm computes a complete 2-by-2 CS decomposition, which requires simultaneous diagonalization of all the four blocks of a unitary/orthogonal matrix partitioned into a 2-by-2 block structure.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Computational Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of an orthogonal/unitary matrix in bidiagonal-block form	bbcsd/bbcsd	bbcsd/bbcsd
Simultaneously bidiagonalize the blocks of a partitioned orthogonal matrix	orbdb unbdb	
Simultaneously bidiagonalize the blocks of a partitioned unitary matrix		orbdb unbdb

Description

mkl_lapack.fi The routine ?bbcsd computes the CS decomposition of an orthogonal or unitary matrix in bidiagonal-block form:

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & & u_2 \end{pmatrix} \begin{pmatrix} C & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & & v_2 \end{pmatrix}^T$$

or

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & & u_2 \end{pmatrix} \begin{pmatrix} C & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & & v_2 \end{pmatrix}^H$$

respectively.

x is m -by- m with the top-left block p -by- q . Note that q must not be larger than p , $m-p$, or $m-q$. If q is not the smallest index, x must be transposed and/or permuted in constant time using the *trans* option. See ? orcsd/?uncsd for details.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are represented implicitly by angles $theta(1:q)$ and $phi(1:q-1)$.

The orthogonal/unitary matrices u_1 , u_2 , v_1^t , and v_2^t are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Input Parameters

<i>jobu1</i>	CHARACTER. If equals Y, then u_1 is updated. Otherwise, u_1 is not updated.
<i>jobu2</i>	CHARACTER. If equals Y, then u_2 is updated. Otherwise, u_2 is not updated.
<i>jobv1t</i>	CHARACTER. If equals Y, then v_1^t is updated. Otherwise, v_1^t is not updated.
<i>jobv2t</i>	CHARACTER. If equals Y, then v_2^t is updated. Otherwise, v_2^t is not updated.
<i>trans</i>	CHARACTER = 'T': x , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order. otherwise x , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order.
<i>m</i>	INTEGER. The number of rows and columns of the orthogonal/unitary matrix X in bidiagonal-block form.
<i>p</i>	INTEGER. The number of rows in the top-left block of x . $0 \leq p \leq m$. \leq
<i>q</i>	INTEGER. The number of columns in the top-left block of x . $0 \leq q \leq \min(p, m-p)$.
<i>theta</i>	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Array, size (q). On entry, the angles $\theta(1), \dots, \theta(q)$ that, along with $\phi(1), \dots, \phi(q-1)$, define the matrix in bidiagonal-block form as returned by orbdb/unbdb .
<i>phi</i>	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Array, size ($q-1$). The angles $\phi(1), \dots, \phi(q-1)$ that, along with $\theta(1), \dots, \theta(q)$, define the matrix in bidiagonal-block form as returned by orbdb/unbdb .
<i>u1</i>	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd

	DOUBLE COMPLEX for zbbcsd Array, size ($ldu1, p$). On entry, a p -by- p matrix.
$ldu1$	INTEGER. The leading dimension of the array u_1 , $ldu1 \leq \max(1, p)$.
$u2$	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Array, size ($ldu2, m-p$). On entry, an $(m-p)$ -by- $(m-p)$ matrix.
$ldu2$	INTEGER. The leading dimension of the array u_2 , $ldu2 \leq \max(1, m-p)$.
$v1t$	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Array, size ($ldv1t, q$). On entry, a q -by- q matrix.
$ldv1t$	INTEGER. The leading dimension of the array $v1t$, $ldv1t \leq \max(1, q)$.
$v2t$	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Array, size ($ldv2t, m-q$). On entry, an $(m-q)$ -by- $(m-q)$ matrix.
$ldv2t$	INTEGER. The leading dimension of the array $v2t$, $ldv2t \leq \max(1, m-q)$.
$work$	REAL for sbbcsd DOUBLE PRECISION for dbbcsd COMPLEX for cbbcsd DOUBLE COMPLEX for zbbcsd Workspace array, size ($\max(1, lwork)$).
$lwork$	INTEGER. The size of the <i>work</i> array. $lwork \geq \max(1, 8*q)$ If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.

When `?bbcsd` converges, `b11d` contains the cosines of $\theta(1), \dots, \theta(q)$. If `?bbcsd` fails to converge, `b11d` contains the diagonal of the partially reduced top left block.

`b11e`

REAL for `sbbcsd`

DOUBLE PRECISION for `dbbcsd`

COMPLEX for `cbbcsd`

DOUBLE COMPLEX for `zbbcsd`

Array, size $(q-1)$.

When `?bbcsd` converges, `b11e` contains zeros. If `?bbcsd` fails to converge, `b11e` contains the superdiagonal of the partially reduced top left block.

`b12d`

REAL for `sbbcsd`

DOUBLE PRECISION for `dbbcsd`

COMPLEX for `cbbcsd`

DOUBLE COMPLEX for `zbbcsd`

Array, size (q) .

When `?bbcsd` converges, `b12d` contains the negative sines of $\theta(1), \dots, \theta(q)$. If `?bbcsd` fails to converge, `b12d` contains the diagonal of the partially reduced top right block.

`b12e`

REAL for `sbbcsd`

DOUBLE PRECISION for `dbbcsd`

COMPLEX for `cbbcsd`

DOUBLE COMPLEX for `zbbcsd`

Array, size $(q-1)$.

When `?bbcsd` converges, `b12e` contains zeros. If `?bbcsd` fails to converge, `b12e` contains the superdiagonal of the partially reduced top right block.

`info`

INTEGER.

= 0: successful exit

< 0: if `info` = $-i$, the i -th argument has an illegal value

> 0: if `?bbcsd` did not converge, `info` specifies the number of nonzero entries in `phi`, and `b11d`, `b11e`, etc. contain the partially reduced matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `?bbcsd` interface are as follows:

`theta` Holds the vector of length q .

`phi` Holds the vector of length $q-1$.

<i>u1</i>	Holds the matrix of size (p,p) .
<i>u2</i>	Holds the matrix of size $(m-p,m-p)$.
<i>v1t</i>	Holds the matrix of size (q,q) .
<i>v2t</i>	Holds the matrix of size $(m-q,m-q)$.
<i>b11d</i>	Holds the vector of length q .
<i>b11e</i>	Holds the vector of length $q-1$.
<i>b12d</i>	Holds the vector of length q .
<i>b12e</i>	Holds the vector of length $q-1$.
<i>b21d</i>	Holds the vector of length q .
<i>b21e</i>	Holds the vector of length $q-1$.
<i>b22d</i>	Holds the vector of length q .
<i>b22e</i>	Holds the vector of length $q-1$.
<i>jobsu1</i>	Indicates whether u_1 is computed. Must be 'Y' or 'O'.
<i>jobsu2</i>	Indicates whether u_2 is computed. Must be 'Y' or 'O'.
<i>jobv1t</i>	Indicates whether v_1^t is computed. Must be 'Y' or 'O'.
<i>jobv2t</i>	Indicates whether v_2^t is computed. Must be 'Y' or 'O'.
<i>trans</i>	Must be 'N' or 'T'.

Description

The routines `?orbdb/?unbdb` simultaneously bidiagonalizes the blocks of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | & \\ & & p_2 \end{pmatrix} \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ & & q_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | & \\ & & p_2 \end{pmatrix} \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ & & q_2 \end{pmatrix}^H$$

x_{11} is p -by- q . q must not be larger than p , $m-p$, or $m-q$. Otherwise, x must be transposed and/or permuted in constant time using the `trans` and `signs` options.

The orthogonal/unitary matrices p_1 , p_2 , q_1 , and q_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. They are represented implicitly by Housholder vectors.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are q -by- q bidiagonal matrices represented implicitly by angles $\theta(1), \dots, \theta(q)$ and $\phi(1), \dots, \phi(q-1)$. b_{11} and b_{12} are upper bidiagonal, while b_{21} and b_{22} are lower bidiagonal. Every entry in each bidiagonal band is a product of a sine or cosine of θ with a sine or cosine of ϕ . See [Sutton09] for details.

p_1 , p_2 , q_1 , and q_2 are represented as products of elementary reflectors. .

Input Parameters

<code>trans</code>	CHARACTER	
= 'T':		x , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order.
otherwise		x , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order.
<code>signs</code>	CHARACTER	
= 'O':		The lower-left block is made nonpositive (the "other" convention).
otherwise		The upper-right block is made nonpositive (the "default" convention).
<code>m</code>	INTEGER.	The number of rows and columns of the matrix X .

p	INTEGER. The number of rows in x_{11} and x_{12} . $0 \leq p \leq m$.
q	INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq \min(p, m-p, m-q)$.
x_{11}	<p>REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb DOUBLE COMPLEX for zunbdb</p> <p>Array, size $(ldx11,*)$.</p> <p>On entry, the top-left block of the orthogonal/unitary matrix to be reduced.</p>
$ldx11$	INTEGER. The leading dimension of the array X_{11} . If $trans = 'T'$, $ldx11 \geq p$. Otherwise, $ldx11 \geq q$.
x_{12}	<p>REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb DOUBLE COMPLEX for zunbdb</p> <p>Array, size $(ldx12, m-q)$.</p> <p>On entry, the top-right block of the orthogonal/unitary matrix to be reduced.</p>
$ldx12$	INTEGER. The leading dimension of the array X_{12} . If $trans = 'N'$, $ldx12 \geq p$. Otherwise, $ldx12 \geq m-q$.
x_{21}	<p>REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb DOUBLE COMPLEX for zunbdb</p> <p>Array, size $(ldx21, q)$.</p> <p>On entry, the bottom-left block of the orthogonal/unitary matrix to be reduced.</p>
$ldx21$	INTEGER. The leading dimension of the array X_{21} . If $trans = 'N'$, $ldx21 \geq m-p$. Otherwise, $ldx21 \geq q$.
x_{22}	<p>REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb DOUBLE COMPLEX for zunbdb</p> <p>Array, size $(ldx22, m-q)$.</p> <p>On entry, the bottom-right block of the orthogonal/unitary matrix to be reduced.</p>

<i>ldx22</i>	INTEGER. The leading dimension of the array X_{21} . If <i>trans</i> = 'N', $ldx22 \geq m - p$. Otherwise, $ldx22 \geq m - q$.
<i>work</i>	REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb DOUBLE COMPLEX for zunbdb Workspace array, size (<i>lwork</i>).
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. $lwork \geq m - q$ If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.

Output Parameters

<i>x11</i>	On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the lower triangle of <i>x11</i> specify reflectors for p_1 , the rows of the upper triangle of <i>x11</i> (1: <i>q</i> - 1, <i>q</i> : <i>q</i> - 1) specify reflectors for q_1 otherwise <i>trans</i> ='T', the rows of the upper triangle of <i>x11</i> specify reflectors for p_1 , the columns of the lower triangle of <i>x11</i> (1: <i>q</i> - 1, <i>q</i> : <i>q</i> - 1) specify reflectors for q_1
<i>x12</i>	On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the upper triangle of <i>x12</i> specify the first p reflectors for q_2 otherwise <i>trans</i> ='T', the columns of the lower triangle of <i>x12</i> specify the first p reflectors for q_2
<i>x21</i>	On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the lower triangle of <i>x21</i> specify the reflectors for p_2 otherwise <i>trans</i> ='T', the columns of the upper triangle of <i>x21</i> specify the reflectors for p_2
<i>x22</i>	On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the rows of the upper triangle of <i>x22</i> ($q+1:m-p, p+1:m-q$) specify the last $m-p-q$ reflectors for q_2 otherwise <i>trans</i> ='T', the columns of the lower triangle of <i>x22</i> ($p+1:m-q, q+1:m-p$) specify the last $m-p-q$ reflectors for p_2
<i>theta</i>	REAL for sorbdb DOUBLE PRECISION for dorbdb COMPLEX for cunbdb

	DOUBLE COMPLEX for zunbdb
	Array, size (q). The entries of bidiagonal blocks b_{11} , b_{12} , b_{21} , and b_{22} can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details.
<i>phi</i>	REAL for sorbdb
	DOUBLE PRECISION for dorbdb
	COMPLEX for cunbdb
	DOUBLE COMPLEX for zunbdb
	Array, size ($q-1$). The entries of bidiagonal blocks b_{11} , b_{12} , b_{21} , and b_{22} can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details.
<i>taup1</i>	REAL for sorbdb
	DOUBLE PRECISION for dorbdb
	COMPLEX for cunbdb
	DOUBLE COMPLEX for zunbdb
	Array, size (p).
	Scalar factors of the elementary reflectors that define p_1 .
<i>taup2</i>	REAL for sorbdb
	DOUBLE PRECISION for dorbdb
	COMPLEX for cunbdb
	DOUBLE COMPLEX for zunbdb
	Array, size ($m-p$).
	Scalar factors of the elementary reflectors that define p_2 .
<i>tauq1</i>	REAL for sorbdb
	DOUBLE PRECISION for dorbdb
	COMPLEX for cunbdb
	DOUBLE COMPLEX for zunbdb
	Array, size (q).
	Scalar factors of the elementary reflectors that define q_1 .
<i>tauq2</i>	REAL for sorbdb
	DOUBLE PRECISION for dorbdb
	COMPLEX for cunbdb
	DOUBLE COMPLEX for zunbdb
	Array, size ($m-q$).
	Scalar factors of the elementary reflectors that define q_2 .
<i>info</i>	INTEGER.
	= 0: successful exit

< 0 : if *info* = $-i$, the i -th argument has an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `?orbdb/?unbdb` interface are as follows:

<i>x11</i>	Holds the block of matrix X of size (p, q) .
<i>x12</i>	Holds the block of matrix X of size $(p, m-q)$.
<i>x21</i>	Holds the block of matrix X of size $(m-p, q)$.
<i>x22</i>	Holds the block of matrix X of size $(m-p, m-q)$.
<i>theta</i>	Holds the vector of length q .
<i>phi</i>	Holds the vector of length $q-1$.
<i>taup1</i>	Holds the vector of length p .
<i>taup2</i>	Holds the vector of length $m-p$.
<i>tauq1</i>	Holds the vector of length q .
<i>taupq2</i>	Holds the vector of length $m-q$.
<i>trans</i>	Must be 'N' or 'T'.
<i>signs</i>	Must be 'O' or 'D'.

Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate [computational routines](#).

Driver routines are described in the following sections :

[Linear Least Squares \(LLS\) Problems](#)

[Generalized LLS Problems](#)

[Symmetric Eigenproblems](#)

[Nonsymmetric Eigenproblems](#)

[Singular Value Decomposition](#)

[Cosine-Sine Decomposition](#)

[Generalized Symmetric Definite Eigenproblems](#)

Generalized Nonsymmetric Eigenproblems

Linear Least Squares (LLS) Problems

This section describes LAPACK driver routines used for solving linear least squares problems. Table "Driver Routines for Solving LLS Problems" lists all such routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving LLS Problems

Routine Name	Operation performed
gels	Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.
gelsy	Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.
gelss	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.
gelsd	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

[?gels](#)

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

```
call sgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call dgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call cgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call zgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call gels(a, b [,trans] [,info])
```

Include Files

- `mk1.fi, lapack.f90`

Description

The routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix A , or its transpose/ conjugate-transpose, using a QR or LQ factorization of A . It is assumed that A has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||b - A*x||_2$$

2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $A^*X = B$.

3. If $trans = 'T'$ or $'C'$ and $m \geq n$: find the minimum norm solution of an undetermined system $A^H * X = B$.

4. If $trans = 'T'$ or $'C'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||b - A^H * x||_2$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are formed by the columns of the right hand side matrix B and the solution matrix X (when coefficient matrix is A , B is m -by- $nrhs$ and X is n -by- $nrhs$; if the coefficient matrix is A^T or A^H , B is n -by- $nrhs$ and X is m -by- $nrhs$).

Input Parameters

<i>trans</i>	<p>CHARACTER*1. Must be 'N', 'T', or 'C'.</p> <p>If <i>trans</i> = 'N', the linear system involves matrix A;</p> <p>If <i>trans</i> = 'T', the linear system involves the transposed matrix A^T (for real flavors only);</p> <p>If <i>trans</i> = 'C', the linear system involves the conjugate-transposed matrix A^H (for complex flavors only).</p>
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	<p>INTEGER. The number of columns of the matrix A</p> <p>($n \geq 0$).</p>
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a, b, work</i>	<p>REAL for sgels</p> <p>DOUBLE PRECISION for dgels</p> <p>COMPLEX for cgels</p> <p>DOUBLE COMPLEX for zgels.</p> <p>Arrays:</p> <p>$a(lda,*)$ contains the m-by-n matrix A.</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>$b ldb,*)$ contains the matrix B of right hand side vectors.</p> <p>The second dimension of b must be at least $\max(1, nrhs)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; must be at least $\max(1, m, n)$.
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array; must be at least $\min(m, n) + \max(1, m, n, nrhs)$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	On exit, overwritten by the factorization data as follows:
----------	--

if $m \geq n$, array a contains the details of the QR factorization of the matrix A as returned by `?geqrf`;

if $m < n$, array a contains the details of the LQ factorization of the matrix A as returned by `?gelqf`.

b If $info = 0$, b overwritten by the solution vectors, stored columnwise:

if $trans = 'N'$ and $m \geq n$, rows 1 to n of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $n+1$ to m in that column;

if $trans = 'N'$ and $m < n$, rows 1 to n of b contain the minimum norm solution vectors;

if $trans = 'T'$ or $'C'$ and $m \geq n$, rows 1 to m of b contain the minimum norm solution vectors;

if $trans = 'T'$ or $'C'$ and $m < n$, rows 1 to m of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $m+1$ to n in that column.

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gels` interface are the following:

a Holds the matrix A of size (m,n) .

b Holds the matrix of size $\max(m,n)$ -by- $nrhs$.

If $trans = 'N'$, then, on entry, the size of b is m -by- $nrhs$,

If $trans = 'T'$, then, on entry, the size of b is n -by- $nrhs$,

$trans$ Must be $'N'$ or $'T'$. The default value is $'N'$.

Application Notes

For better performance, try using $lwork = \min(m, n) + \max(1, m, n, nrhs) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.

Syntax

```
call sgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call dgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call cgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork, info)
call zgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork, info)
call gelsy(a, b [,rank] [,jpvt] [,rcond] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The ?gelsy routine computes the minimum-norm solution to a real/complex linear least squares problem:

minimize $\|b - A \cdot x\|_2$

using a complete orthogonal factorization of *A*. *A* is an *m*-by-*n* matrix which may be rank-deficient. Several right hand side vectors *b* and solution vectors *x* can be handled in a single call; they are stored as the columns of the *m*-by-*nrhs* right hand side matrix *B* and the *n*-by-*nrhs* solution matrix *X*.

The routine first computes a *QR* factorization with column pivoting:

$$A P = \begin{pmatrix} R_{11} & R_{12} \\ 0 & 0 \end{pmatrix} \begin{pmatrix} Q_1^T \\ Q_2^T \end{pmatrix}$$

with R_{11} defined as the largest leading submatrix whose estimated condition number is less than $1/rcond$. The order of R_{11} , *rank*, is the effective rank of *A*. Then, R_{22} is considered to be negligible, and R_{12} is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A P = Q \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^T \begin{pmatrix} T_{11}^{-1} Q_1^T B \\ 0 \end{pmatrix} \text{ for real flavors and}$$

$$X = PZ^H \begin{pmatrix} T_{11}^{-1} Q_1^H B \\ 0 \end{pmatrix} \text{ for complex flavors,}$$

where Q_1 consists of the first *rank* columns of Q .

The `?gelsy` routine is identical to the original deprecated `?gelsx` routine except for the following differences:

- The call to the subroutine `?geqpf` has been substituted by the call to the subroutine `?geqp3`, which is a BLAS-3 version of the *QR* factorization with column pivoting.
- The matrix B (the right hand side) is updated with BLAS-3.
- The permutation of the matrix B (the right hand side) is faster and more simple.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	<p>REAL for <code>sgelsy</code></p> <p>DOUBLE PRECISION for <code>dgelsy</code></p> <p>COMPLEX for <code>cgelsy</code></p> <p>DOUBLE COMPLEX for <code>zgelsy</code>.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the m-by-n matrix A.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the m-by-<i>nrhs</i> right hand side matrix B.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>jpvt</i>	<p>INTEGER.</p> <p>Array, size at least $\max(1, n)$.</p> <p>On entry, if <i>jpvt</i>(<i>i</i>) $\neq 0$, the <i>i</i>-th column of A is permuted to the front of AP, otherwise the <i>i</i>-th column of A is a free column.</p>

<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of <i>A</i> , which is defined as the order of the largest leading triangular submatrix R_{11} in the <i>QR</i> factorization with pivoting of <i>A</i> , whose estimated condition number $< 1/rcond$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <i>cgelsy</i> DOUBLE PRECISION for <i>zgelsy</i> . Workspace array, size at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	On exit, overwritten by the details of the complete orthogonal factorization of <i>A</i> .
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>jpvt</i>	On exit, if <i>jpvt</i> (<i>i</i>) = <i>k</i> , then the <i>i</i> -th column of <i>AP</i> was the <i>k</i> -th column of <i>A</i> .
<i>rank</i>	INTEGER. The effective rank of <i>A</i> , that is, the order of the submatrix R_{11} . This is the same as the order of the submatrix T_{11} in the complete orthogonal factorization of <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *gelsy* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>b</i>	Holds the matrix of size $\max(m,n)$ -by- <i>nrhs</i> . On entry, contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>jpvt</i>	Holds the vector of length <i>n</i> . Default value for this element is <i>jpvt</i> (<i>i</i>) = 0.
<i>rcond</i>	Default value for this element is <i>rcond</i> = 100*EPSILON(1.0_wp).

Application Notes

For real flavors:

The unblocked strategy requires that:

$lwork \geq \max(mn+3n+1, 2*mn + nrhs),$

where $mn = \min(m, n)$.

The block algorithm requires that:

$lwork \geq \max(mn+2n+nb*(n+1), 2*mn+nb*nrhs),$

where nb is an upper bound on the blocksize returned by [ilaenv](#) for the routines `sgeqp3/dgeqp3`, `stzrzf/dtzrzf`, `stzrqf/dtzrqf`, `sormqr/dormqr`, and `sormrz/dormrz`.

For complex flavors:

The unblocked strategy requires that:

$lwork \geq mn + \max(2*mn, n+1, mn + nrhs),$

where $mn = \min(m, n)$.

The block algorithm requires that:

$lwork < mn + \max(2*mn, nb*(n+1), mn+mn*nb, mn+ nb*nrhs),$

where nb is an upper bound on the blocksize returned by [ilaenv](#) for the routines `cgeqp3/zgeqp3`, `ctzrzf/ztzrzf`, `ctzrqf/ztzrqf`, `cunmqr/zunmqr`, and `cunmrz/zunmrz`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelss

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.

Syntax

```
call sgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call dgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call cgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, info)
call zgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, info)
call gelss(a, b [,rank] [,s] [,rcond] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes the minimum norm solution to a real linear least squares problem:

minimize $\|b - A*x\|_2$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X . The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
$a, b, work$	REAL for <code>sgelss</code> DOUBLE PRECISION for <code>dgelss</code> COMPLEX for <code>cgelss</code> DOUBLE COMPLEX for <code>zgelss</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the m -by- $nrhs$ right hand side matrix B . The second dimension of b must be at least $\max(1, nrhs)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The leading dimension of b ; must be at least $\max(1, m, n)$.
$rcond$	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. $rcond$ is used to determine the effective rank of A . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond < 0$, machine precision is used instead.
$lwork$	INTEGER. The size of the $work$ array; $lwork \geq 1$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla . See <i>Application Notes</i> for the suggested value of $lwork$.
$rwork$	REAL for <code>cgelss</code> DOUBLE PRECISION for <code>zgelss</code> .

Workspace array used in complex flavors only. size at least $\max(1, 5*\min(m, n))$.

Output Parameters

<i>a</i>	On exit, the first $\min(m, n)$ rows of <i>a</i> are overwritten with the matrix of right singular vectors of <i>A</i> , stored row-wise.
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the <i>i</i> -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, size at least $\max(1, \min(m, n))$. The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$.
<i>rank</i>	INTEGER. The effective rank of <i>A</i> , that is, the number of singular values which are greater than $rcond * s(1)$.
<i>work</i> (1)	If $info = 0$, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value. If $info = i$, then the algorithm for computing the SVD failed to converge; <i>i</i> indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gelss` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . On entry, contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>s</i>	Holds the vector of length $\min(m, n)$.
<i>rcond</i>	Default value for this element is $rcond = 100 * \text{EPSILON}(1.0_WP)$.

Application Notes

For real flavors:

$lwork \geq 3 * \min(m, n) + \max(2 * \min(m, n), \max(m, n), nrhs)$

For complex flavors:

$lwork \geq 2 * \min(m, n) + \max(m, n, nrhs)$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

sgelsd

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

Syntax

```
call sgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)
call dgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)
call cgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, iwork, info)
call zgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, iwork, info)
call gelsd(a, b [,rank] [,s] [,rcond] [,info])
```

Include Files

Description

The routine computes the minimum-norm solution to a real linear least squares problem:

minimize $\|b - A*x\|_2$

using the singular value decomposition (SVD) of *A*. *A* is an *m*-by-*n* matrix which may be rank-deficient.

Several right hand side vectors *b* and solution vectors *x* can be handled in a single call; they are stored as the columns of the *m*-by-*nrhs* right hand side matrix *B* and the *n*-by-*nrhs* solution matrix *X*.

The problem is solved in three steps:

1. Reduce the coefficient matrix *A* to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).
2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of *A* is determined by treating as zero those singular values which are less than *rcond* times the largest singular value.

The routine uses auxiliary routines [lals0](#) and [lalsa](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	<p>REAL for <i>sgelsd</i> DOUBLE PRECISION for <i>dgelsd</i> COMPLEX for <i>cgelsd</i> DOUBLE COMPLEX for <i>zgelsd</i>.</p> <p>Arrays: <i>a</i>(<i>lda</i>,*) contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>. <i>iwork</i>	INTEGER. Workspace array. See <i>Application Notes</i> for the suggested dimension of <i>iwork</i> .
<i>rwork</i>	<p>REAL for <i>cgelsd</i> DOUBLE PRECISION for <i>zgelsd</i>.</p> <p>Workspace array, used in complex flavors only. See <i>Application Notes</i> for the suggested dimension of <i>rwork</i>.</p>

Output Parameters

<i>a</i>	On exit, <i>A</i> has been overwritten.
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the <i>i</i> -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, size at least $\max(1, \min(m, n))$. The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n)).$
<i>rank</i>	INTEGER. The effective rank of <i>A</i> , that is, the number of singular values which are greater than $rcond * s(1)$.
<i>work</i> (1)	If <i>info</i> = 0, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>rwork</i> (1)	If <i>info</i> = 0, on exit, <i>rwork</i> (1) returns the minimum size of the workspace array <i>iwork</i> required for optimum performance.
<i>iwork</i> (1)	If <i>info</i> = 0, on exit, <i>iwork</i> (1) returns the minimum size of the workspace array <i>iwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm for computing the SVD failed to converge; <i>i</i> indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gelsd` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>b</i>	Holds the matrix of size $\max(m,n)$ -by- <i>nrhs</i> . On entry, contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>s</i>	Holds the vector of length $\min(m,n)$.
<i>rcond</i>	Default value for this element is $rcond = 100 * EPSILON(1.0_WP)$.

Application Notes

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

The exact minimum amount of workspace needed depends on m , n and $nrhs$. The size $lwork$ of the workspace array $work$ must be as given below.

For real flavors:

If $m \geq n$,

$$lwork \geq 12n + 2n*smlsiz + 8n*nlvl + n*nrhs + (smlsiz+1)^2;$$

If $m < n$,

$$lwork \geq 12m + 2m*smlsiz + 8m*nlvl + m*nrhs + (smlsiz+1)^2;$$

For complex flavors:

If $m \geq n$,

$$lwork < 2n + n*nrhs;$$

If $m < n$,

$$lwork \geq 2m + m*nrhs;$$

where $smlsiz$ is returned by `ilaenv` and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and

$$nlvl = \text{INT}(\log_2(\min(m, n)/(smlsiz+1))) + 1.$$

For good performance, $lwork$ should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The dimension of the workspace array $iwork$ must be at least

$$3*\min(m, n)*nlvl + 11*\min(m, n).$$

The dimension of the workspace array $iwork$ (for complex flavors) must be at least $\max(1, lrwork)$.

$$lrwork \geq 10n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m \geq n, \text{ and}$$

$$lrwork \geq 10m + 2m*smlsiz + 8m*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m < n.$$

Generalized LLS Problems

This section describes LAPACK driver routines used for solving generalized linear least squares problems. [Table "Driver Routines for Solving Generalized LLS Problems"](#) lists all such routines. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized LLS Problems

Routine Name	Operation performed
gglse	Solves the linear equality-constrained least squares problem using a generalized RQ factorization.
ggglm	Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

?gglse

Solves the linear equality-constrained least squares problem using a generalized RQ factorization.

Syntax

```
call sgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call dgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call cgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call zgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call gglse(a, b, c, d, x [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } ||c - A*x||^2 \text{ subject to } B*x = d$$

where A is an m -by- n matrix, B is a p -by- n matrix, c is a given m -vector, and d is a given p -vector. It is assumed that $p \leq n \leq m + p$, and

$$B = \begin{bmatrix} B_{11} & B_{12} \\ 0 & I_p \end{bmatrix}, \quad A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices $\begin{pmatrix} B \\ A \end{pmatrix}$ given by

$$B = \begin{pmatrix} 0 & R \end{pmatrix} * Q, \quad A = Z * T * Q$$

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
p	INTEGER. The number of rows of the matrix B ($0 \leq p \leq n \leq m + p$).
$a, b, c, d, work$	REAL for sgglse

DOUBLE PRECISION for `dgglse`

COMPLEX for `cgglse`

DOUBLE COMPLEX for `zgglse`.

Arrays:

$a(lda,*)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$b(ldb,*)$ contains the p -by- n matrix B .

The second dimension of b must be at least $\max(1, n)$.

$c(*)$, size at least $\max(1, m)$, contains the right hand side vector for the least squares part of the LSE problem.

$d(*),,$ size at least $\max(1, p)$, contains the right hand side vector for the constrained equation.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, p)$.

$lwork$ INTEGER. The size of the $work$ array;

$lwork \geq \max(1, m+n+p)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a The elements on and above the diagonal contain the $\min(m, n)$ -by- n upper trapezoidal matrix T as returned by `?ggrqf`.

x REAL for `sgglse`
The solution of the LSE problem.

b On exit, the upper right triangle of the subarray $b(1:p, n-p+1:n)$ contains the p -by- p upper triangular matrix R as returned by `?ggrqf`.

d On exit, d is destroyed.

c On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements $n-p+1$ to m of vector c .

$work(1)$ If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that $rank(B) < p$; the least squares solution could not be computed.

If $info = 2$, the $(n-p)$ -by- $(n-p)$ part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that

$$rank \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gglsse` interface are the following:

a	Holds the matrix A of size (m,n) .
b	Holds the matrix B of size (p,n) .
c	Holds the vector of length (m) .
d	Holds the vector of length (p) .
x	Holds the vector of length n .

Application Notes

For optimum performance, use

$$lwork \geq p + \min(m, n) + \max(m, n) * nb,$$

where nb is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrq`.

You may set $lwork$ to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

Syntax

```
call sggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call dggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call cggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call zggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call ggglm(a, b, d, x, y [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine solves a general Gauss-Markov linear model (GLM) problem:

$$\text{minimize}_x ||y||_2 \text{ subject to } d = A^*x + B^*y$$

where A is an n -by- m matrix, B is an n -by- p matrix, and d is a given n -vector. It is assumed that $m \leq n \leq m+p$, and $\text{rank}(A) = m$ and $\text{rank}(AB) = n$.

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y , which is obtained using a generalized QR factorization of the matrices (A, B) given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q * T * Z.$$

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\text{minimize}_x ||B^{-1}(d - A^*x)||_2.$$

Input Parameters

n	INTEGER. The number of rows of the matrices A and B ($n \geq 0$).
m	INTEGER. The number of columns in A ($m \geq 0$).
p	INTEGER. The number of columns in B ($p \geq n - m$).
$a, b, d, work$	REAL for sggglm DOUBLE PRECISION for dggglm COMPLEX for cggglm DOUBLE COMPLEX for zggglm. Arrays: $a(lda,*)$ contains the n -by- m matrix A . The second dimension of a must be at least $\max(1, m)$. $b(l db,*)$ contains the n -by- p matrix B . The second dimension of b must be at least $\max(1, p)$. $d(*)$, size at least $\max(1, n)$, contains the left hand side of the GLM equation. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
ldb	INTEGER. The leading dimension of b ; at least $\max(1, n)$.
$lwork$	INTEGER. The size of the $work$ array; $lwork \geq \max(1, n+m+p)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

x, y	<p>REAL for sggglm</p> <p>DOUBLE PRECISION for dggglm</p> <p>COMPLEX for cggglm</p> <p>DOUBLE COMPLEX for zggglm.</p> <p>Arrays $x(*)$, $y(*)$. size at least $\max(1, m)$ for x and at least $\max(1, p)$ for y. On exit, x and y are the solutions of the GLM problem.</p>
a	On exit, the upper triangular part of the array a contains the m -by- m upper triangular matrix R .
b	On exit, if $n \leq p$, the upper right triangle of the subarray $b(1:n, p-n+1:p)$ contains the n -by- n upper triangular matrix T as returned by ?ggrqf ; if $n > p$, the elements on and above the $(n-p)$ -th subdiagonal contain the n -by- p upper trapezoidal matrix T .
d	On exit, d is destroyed
$work(1)$	If $info = 0$, on exit, $work(1)$ contains the minimum value of <i>lwork</i> required for optimum performance.
$info$	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = 1$, the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that $\text{rank}(A) < m$; the least squares solution could not be computed.</p> <p>If $info = 2$, the bottom $(n-m)$-by-$(n-m)$ part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that $\text{rank}(AB) < n$; the least squares solution could not be computed.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine [ggglm](#) interface are the following:

a	Holds the matrix A of size (n, m) .
b	Holds the matrix B of size (n, p) .

d	Holds the vector of length n .
x	Holds the vector of length (m) .
y	Holds the vector of length (p) .

Application Notes

For optimum performance, use

$$lwork \geq m + \min(n, p) + \max(n, p) * nb,$$

where nb is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrq`.

You may set $lwork$ to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Symmetric Eigenproblems

This section describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Symmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Symmetric Eigenproblems

Routine Name	Operation performed
syev / heev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix.
syevd / heevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm.
syevx / heevx	Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix.
syevr / heevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations.
spev / hpev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
spevd / hpevd	Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage.
spevx / hpevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
sbev / hbev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
sbevd / hbevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm.
sbevx / hbevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
stev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

Routine Name	Operation performed
stevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.
stevx	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
stevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

?syev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

Syntax

```
call ssyev(jobz, uplo, n, a, lda, w, work, lwork, info)
call dsyev(jobz, uplo, n, a, lda, w, work, lwork, info)
call syev(a, w [,jobz] [,uplo] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A .

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for <i>ssyev</i></p> <p>DOUBLE PRECISION for <i>dsyev</i></p> <p><i>a(lda,*)</i> is an array containing either upper or lower triangular part of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p>

Must be at least $\max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

Constraint: $lwork \geq \max(1, 3n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, array *a* contains the orthonormal eigenvectors of the matrix *A*.

If $jobz = 'N'$, then on exit the lower triangle

(if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of *A*, including the diagonal, is overwritten.

w

REAL for *ssyev*

DOUBLE PRECISION for *dsyev*

Array, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order.

work(1)

On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *syev* interface are the following:

a

Holds the matrix *A* of size (n, n) .

w

Holds the vector of length *n*.

job

Must be 'N' or 'V'. The default value is 'N'.

uplo

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance set $lwork \geq (nb+2) * n$, where nb is the blocksize for `?sytrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

If $lwork$ has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array $work$. This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?heev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call cheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
call zheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
call heev(a, w [,jobz] [,uplo] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `heevr` function as its underlying algorithm is faster and uses less workspace.

Input Parameters

jobz CHARACTER*1. Must be 'N' or 'V'.
 If $jobz = 'N'$, then only eigenvalues are computed.
 If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	<p>COMPLEX for <i>cheev</i></p> <p>DOUBLE COMPLEX for <i>zheev</i></p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>. C</p> <p>onstraint: $lwork \geq \max(1, 2n-1)$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>rwork</i>	<p>REAL for <i>cheev</i></p> <p>DOUBLE PRECISION for <i>zheev</i>.</p> <p>Workspace array, size at least $\max(1, 3n-2)$.</p>

Output Parameters

<i>a</i>	<p>On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix <i>A</i>.</p> <p>If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i>, including the diagonal, is overwritten.</p>
<i>w</i>	<p>REAL for <i>cheev</i></p> <p>DOUBLE PRECISION for <i>zheev</i></p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.</p>
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `heev` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>job</code>	Must be 'N' or 'V'. The default value is 'N'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use

$lwork \geq (nb+1) * n$,

where nb is the blocksize for `?hetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?syevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Syntax

```
call ssyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
```

```
call dsyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
```

```
call syevd(a, w [,jobz] [,uplo] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. `?syevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>a</i>	<p>REAL for <code>ssyevd</code></p> <p>DOUBLE PRECISION for <code>dsyevd</code></p> <p>Array, size (<i>lda</i>, *).</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p> <p>Must be at least $\max(1, n)$.</p>
<i>work</i>	<p>REAL for <code>ssyevd</code></p> <p>DOUBLE PRECISION for <code>dsyevd</code>.</p> <p>Workspace array, size at least <i>lwork</i>.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>if $n \leq 1$, then $lwork \geq 1$;</p> <p>if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq 2*n + 1$;</p> <p>if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq 2*n^2 + 6*n + 1$.</p>

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for ssyevd

DOUBLE PRECISION for dsyevd

Array, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

a

If $jobz = 'V'$, then on exit this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*.

work(1)

On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

iwork(1)

On exit, if $liwork > 0$, then *iwork*(1) returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; *i* indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$.

If $info = -i$, the *i*-th parameter had an illegal value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `syevd` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>jobz</code>	Must be 'N' or 'V'. The default value is 'N'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run, or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`) on exit. Use this value (`work(1)`, `iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [heevd](#)

?heevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Syntax

```
call cheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork, liwork, info)
call zheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork, liwork, info)
call heevd(a, w [,job] [,uplo] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$A * z_i = \lambda_i * z_i$ for $i = 1, 2, \dots, n$.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace. `?heevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	<p>COMPLEX for <code>cheevd</code></p> <p>DOUBLE COMPLEX for <code>zheevd</code></p> <p>Array, size (<i>lda</i>, *).</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>work</i>	<p>COMPLEX for <code>cheevd</code></p> <p>DOUBLE COMPLEX for <code>zheevd</code>.</p> <p>Workspace array, size $\max(1, lwork)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>. Constraints:</p> <p>if $n \leq 1$, then $lwork \geq 1$;</p> <p>if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq n+1$;</p> <p>if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq n^2+2*n$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>
<i>rwork</i>	<p>REAL for <code>cheevd</code></p> <p>DOUBLE PRECISION for <code>zheevd</code></p>

Workspace array, size at least $lrwork$.

lrwork

INTEGER.

The dimension of the array *rwork*. Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $job = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $job = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*. Constraints: if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for *cheevd*

DOUBLE PRECISION for *zheevd*

Array, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

a

If $jobz = 'V'$, then on exit this array is overwritten by the unitary matrix *Z* which contains the eigenvectors of *A*.

work(1)

On exit, if $lwork > 0$, then the real part of *work*(1) returns the required minimal size of *lwork*.

rwork(1)

On exit, if $lrwork > 0$, then *rwork*(1) returns the required minimal size of *lrwork*.

iwork(1)

On exit, if $liwork > 0$, then *iwork*(1) returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $mod(info, n+1)$.

If $info = -i$, the i -th parameter had an illegal value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `heevd` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>w</i>	Holds the vector of length (n) .
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [syevd](#). See also [hpevd](#) for matrices held in packed storage, and [hbevd](#) for banded matrices.

?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

```
call ssyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, iwork, ifail, info)
```

```
call dsyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, iwork, ifail, info)
```

```
call syevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. `?syevx` is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A', 'V', or 'I'.</p> <p>If <i>range</i> = 'A', all eigenvalues will be found.</p> <p>If <i>range</i> = 'V', all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for <code>ssyevx</code></p> <p>DOUBLE PRECISION for <code>dsyevx</code>.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. Must be at least $\max(1, n)$.</p>
<i>vl, vu</i>	<p>REAL for <code>ssyevx</code></p> <p>DOUBLE PRECISION for <code>dsyevx</code>.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.</p>

<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned.</p> <p>Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$.</p> <p>Not referenced if <i>range</i> = 'A' or 'V'.</p>
<i>abstol</i>	<p>REAL for ssyevx DOUBLE PRECISION for dsyevx.</p> <p>The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$.</p> <p>If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>If $n \leq 1$ then $lwork \geq 1$, otherwise $lwork = 8 * n$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>iwork</i>	<p>INTEGER. Workspace array, size at least $\max(1, 5n)$.</p>
Output Parameters	
<i>a</i>	<p>On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i>, including the diagonal, is overwritten.</p>
<i>m</i>	<p>INTEGER. The total number of eigenvalues found;</p> <p>$0 \leq m \leq n$.</p> <p>If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.</p>
<i>w</i>	<p>REAL for ssyevx DOUBLE PRECISION for dsyevx</p> <p>Array, size at least $\max(1, n)$. The first <i>m</i> elements contain the selected eigenvalues of the matrix <i>A</i> in ascending order.</p>
<i>z</i>	<p>REAL for ssyevx DOUBLE PRECISION for dsyevx.</p> <p>Array <i>z</i>(<i>ldz</i>,*) contains eigenvectors.</p> <p>The second dimension of <i>z</i> must be at least $\max(1, m)$.</p>

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

work(1) On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

ifail INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, then *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'V'$, then *ifail* is not referenced.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *syevx* interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>a</i>	Holds the matrix A of size (m, n) .
<i>ifail</i>	Holds the vector of length n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vu)$.
<i>il</i>	Default value for this argument is $il = 1$.

<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+3) * n$, where *nb* is the maximum of the blocksize for ?sytrd and ?ormtr returned by ilaenv.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If *lwork* has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array *work*. This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||$ is used as tolerance, where $||T||$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{lamch}('S')$.

?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call cheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, rwork, iwork, ifail, info)
```

```
call zheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz, work,
lwork, rwork, iwork, ifail, info)
```

```
call heevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace. `?heevx` is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A', 'V', or 'I'.</p> <p>If <i>range</i> = 'A', all eigenvalues will be found.</p> <p>If <i>range</i> = 'V', all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>a, work</i>	<p>COMPLEX for <code>cheevx</code></p> <p>DOUBLE COMPLEX for <code>zheevx</code>.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. Must be at least $\max(1, n)$.</p>
<i>vl, vu</i>	<p>REAL for <code>cheevx</code></p> <p>DOUBLE PRECISION for <code>zheevx</code>.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints:</p> <p>$1 \leq il \leq iu \leq n$, if $n > 0$; <i>il</i> = 1 and <i>iu</i> = 0, if $n = 0$. Not referenced if <i>range</i> = 'A' or 'V'.</p>

<i>abstol</i>	<p>REAL for cheevx</p> <p>DOUBLE PRECISION for zheevx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$.</p> <p>If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>$lwork \geq 1$ if $n \leq 1$; otherwise at least $2 * n$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>rwork</i>	<p>REAL for cheevx</p> <p>DOUBLE PRECISION for zheevx.</p> <p>Workspace array, size at least $\max(1, 7n)$.</p>
<i>iwork</i>	<p>INTEGER. Workspace array, size at least $\max(1, 5n)$.</p>

Output Parameters

<i>a</i>	<p>On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i>, including the diagonal, is overwritten.</p>
<i>m</i>	<p>INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.</p> <p>If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.</p>
<i>w</i>	<p>REAL for cheevx</p> <p>DOUBLE PRECISION for zheevx</p> <p>Array, size $\max(1, n)$. The first <i>m</i> elements contain the selected eigenvalues of the matrix <i>A</i> in ascending order.</p>
<i>z</i>	<p>COMPLEX for cheevx</p> <p>DOUBLE COMPLEX for zheevx.</p> <p>Array <i>z</i>(<i>ldz</i>,*) contains eigenvectors.</p> <p>The second dimension of <i>z</i> must be at least $\max(1, m)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>).</p> <p>If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>.</p>

If $jobz = 'N'$, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

work(1)

On exit, if $lwork > 0$, then *work(1)* returns the required minimal size of *lwork*.

ifail

INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, then *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'V'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `heevx` interface are the following:

a Holds the matrix A of size (n, n) .

w Holds the vector of length n .

z Holds the matrix Z of size (n, n) .

ifail Holds the vector of length n .

uplo Must be 'U' or 'L'. The default value is 'U'.

vl Default value for this element is $vl = -\text{HUGE}(vl)$.

vu Default value for this element is $vu = \text{HUGE}(vl)$.

il Default value for this argument is $il = 1$.

iu Default value for this argument is $iu = n$.

abstol Default value for this element is $abstol = 0.0_WP$.

jobz Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if *ifail* is present and z is omitted.

range Restored based on the presence of arguments *vl*, *vu*, *il*, *iu* as follows: *range* = 'V', if one of or both *vl* and *vu* are present, *range* = 'I', if one of or both *il* and *iu* are present, *range* = 'A', if none of *vl*, *vu*, *il*, *iu* is present, Note that there will be an error condition if one of or both *vl* and *vu* are present and at the same time one of or both *il* and *iu* are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the maximum of the blocksize for ?hetrd and ?unmtr returned by [ilaenv](#).

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||$ will be used in its place, where $||T||$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \lambda_{\text{mach}}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \lambda_{\text{mach}}('S')$.

?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.

Syntax

```
call ssyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, iwork, liwork, info)

call dsyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, iwork, liwork, info)

call syevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix *A* to tridiagonal form *T*. Then, whenever possible, ?syevr calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stemr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L * D * L^T$ representations

(also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of T :

- a. Compute $T - \sigma^* I = L^* D^* L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b. Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c. For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d. For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?syevr` calls `stemr` when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. `?syevr` calls `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Note that `?syevr` is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I' and $iu - il < n - 1$, <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for <code>ssyevr</code> DOUBLE PRECISION for <code>dsyevr</code> . Arrays: <i>a(lda,*)</i> is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

vl, vu

REAL for `ssyevr`

DOUBLE PRECISION for `dsyevr`.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu

INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint:

$1 \leq il \leq iu \leq n$, if $n > 0$;

$il=1$ and $iu=0$, if $n = 0$.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

$abstol$

REAL for `ssyevr`

DOUBLE PRECISION for `dsyevr`. The absolute error tolerance to which each eigenvalue/eigenvector is required.

If $jobz = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $abstol$, and the dot products between different eigenvectors are bounded by $abstol$.

If $abstol < n * \epsilon * ||T||$, then $n * \epsilon * ||T||$ is used instead, where ϵ is the machine precision, and $||T||$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\epsilon * ||T||$ irrespective of $abstol$.

If high relative accuracy is important, set $abstol$ to `?lamch('S')`.

ldz

INTEGER. The leading dimension of the output array z .

Constraints:

$ldz \geq 1$ if $jobz = 'N'$ and

$ldz \geq \max(1, n)$ if $jobz = 'V'$.

$lwork$

INTEGER.

The dimension of the array $work$.

Constraint: $lwork \geq \max(1, 26n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.

The dimension of the array *iwork*, $lwork \geq \max(1, 10n)$.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by [xerbla](#).

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If *range* = 'A', *m* = *n*, if *range* = 'I', *m* = *iu-il*+1, and if *range* = 'V' the exact value of *m* is not known in advance.

w, *z* REAL for ssyevr
DOUBLE PRECISION for dsyevr.

Arrays:

w(*), size at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in *w*(1) to *w*(*m*);

z(*ldz*,*), the second dimension of *z* must be at least $\max(1, m)$.

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

If *jobz* = 'N', then *z* is not referenced. Note that you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

isuppz INTEGER.

Array, size at least $2 * \max(1, m)$.

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*(2*i*-1) through *isuppz*(2*i*). Referenced only if eigenvectors are needed (*jobz* = 'V') and all eigenvalues are needed, that is, *range* = 'A' or *range* = 'I' and *il* = 1 and *iu* = *n*.

work(1) On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

iwork(1) On exit, if *info* = 0, then *iwork*(1) returns the required minimal size of *liwork*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, an internal error has occurred.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `syevr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length (2* <i>m</i>), where the values (2* <i>m</i>) are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+6)*n$, where *nb* is the maximum of the blocksize for `?sytrd` and `?ormtr` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.

Syntax

```
call cheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)

call zheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z, ldz,
isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)

call heevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

Include Files

- `mk1.fi, lapack.f90`

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to [hetrd](#). Then, whenever possible, `?heevr` calls [stegr](#) to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of T :

- Compute $T - \sigma I = L^*D^*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?heevr` calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `?heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> <p>For <i>range</i> = 'V' or 'I', sstebz/dstebz and cstein/zstein are called.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>COMPLEX for cheevr</p> <p>DOUBLE COMPLEX for zheevr.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p> <p>Must be at least $\max(1, n)$.</p>
<i>vl, vu</i>	<p>REAL for cheevr</p> <p>DOUBLE PRECISION for zheevr.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>REAL for cheevr</p> <p>DOUBLE PRECISION for zheevr.</p>

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If $jobz = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $abstol$, and the dot products between different eigenvectors are bounded by $abstol$.

If $abstol < n * \epsilon * ||T||$, then $n * \epsilon * ||T||$ is used instead, where ϵ is the machine precision, and $||T||$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\epsilon * ||T||$ irrespective of $abstol$.

If high relative accuracy is important, set $abstol$ to $?lamch('S')$.

ldz

INTEGER. The leading dimension of the output array *z*. Constraints:

$ldz \geq 1$ if $jobz = 'N'$;

$ldz \geq \max(1, n)$ if $jobz = 'V'$.

lwork

INTEGER.

The dimension of the array *work*.

Constraint: $lwork \geq \max(1, 2n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

rwork

REAL for *cheevr*

DOUBLE PRECISION for *zheevr*.

Workspace array, size $\max(1, lwork)$.

lrwork

INTEGER.

The dimension of the array *rwork*;

$lrwork \geq \max(1, 24n)$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

iwork

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*,

$liwork \geq \max(1, 10n)$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	<p>INTEGER. The total number of eigenvalues found,</p> <p>$0 \leq m \leq n$.</p> <p>If <i>range</i> = 'A', <i>m</i> = <i>n</i>, if <i>range</i> = 'I', <i>m</i> = <i>iu-il</i>+1, and if <i>range</i> = 'V' the exact value of <i>m</i> is not known in advance.</p>
<i>w</i>	<p>REAL for <i>cheevr</i></p> <p>DOUBLE PRECISION for <i>zheevr</i>.</p> <p>Array, size at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in <i>w</i>(1) to <i>w</i>(<i>m</i>).</p>
<i>z</i>	<p>COMPLEX for <i>cheevr</i></p> <p>DOUBLE COMPLEX for <i>zheevr</i>.</p> <p>Array <i>z</i>(<i>ldz</i>,*), the second dimension of <i>z</i> must be at least $\max(1, m)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>).</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p> <p>Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.</p>
<i>isuppz</i>	<p>INTEGER.</p> <p>Array, size at least $2 * \max(1, m)$.</p> <p>The support of the eigenvectors in <i>z</i>, i.e., the indices indicating the nonzero elements in <i>z</i>. The <i>i</i>-th eigenvector is nonzero only in elements <i>isuppz</i>(2<i>i</i>-1) through <i>isuppz</i>(2<i>i</i>). Referenced only if eigenvectors are needed (<i>jobz</i> = 'V') and all eigenvalues are needed, that is, <i>range</i> = 'A' or <i>range</i> = 'I' and <i>il</i> = 1 and <i>iu</i> = <i>n</i>.</p>
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = <i>i</i>, an internal error has occurred.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `heevr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values n and m are significant.
<i>isuppz</i>	Holds the vector of length $(2*n)$, where the values $(2*m)$ are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present. Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the maximum of the blocksize for `?hetrd` and `?unmtr` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *lrwork*, or *liwork*) for the first run or set $lwork = -1$ ($lrwork = -1$, $liwork = -1$).

If you choose the first option and set any of admissible *lwork* (or *lrwork*, *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*) on exit. Use this value ($work(1)$, $rwork(1)$, $iwork(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*lrwork*, *liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of `?stemr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?spev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

```
call sspev(jobz, uplo, n, ap, w, z, ldz, work, info)
call dspev(jobz, uplo, n, ap, w, z, ldz, work, info)
call spev(ap, w [,uplo] [,z] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Input Parameters

<code>jobz</code>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <code>job = 'N'</code>, then only eigenvalues are computed.</p> <p>If <code>job = 'V'</code>, then eigenvalues and eigenvectors are computed.</p>
<code>uplo</code>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <code>uplo = 'U'</code>, <code>ap</code> stores the packed upper triangular part of A.</p> <p>If <code>uplo = 'L'</code>, <code>ap</code> stores the packed lower triangular part of A.</p>
<code>n</code>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<code>ap, work</code>	<p>REAL for <code>sspev</code></p> <p>DOUBLE PRECISION for <code>dspev</code></p> <p>Arrays:</p> <p>Array <code>ap(*)</code> contains the packed upper or lower triangle of symmetric matrix A, as specified by <code>uplo</code>.</p> <p>The size of <code>ap</code> must be at least $\max(1, n*(n+1)/2)$.</p> <p><code>work(*)</code> is a workspace array, size at least $\max(1, 3n)$.</p>

ldz INTEGER. The leading dimension of the output array *z*. Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w, z REAL for *sspev*
 DOUBLE PRECISION for *dspev*
 Arrays:
w(*), size at least $\max(1, n)$.
 If *info* = 0, *w* contains the eigenvalues of the matrix *A* in ascending order.
z(*ldz*,*), The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If *jobz* = 'N', then *z* is not referenced.

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *spev* interface are the following:

ap Holds the array *A* of size $(n*(n+1)/2)$.
w Holds the vector with the number of elements *n*.
z Holds the matrix *Z* of size (n, n) .
uplo Must be 'U' or 'L'. The default value is 'U'.
jobz Restored based on the presence of the argument *z* as follows: *jobz* = 'V', if *z* is present, *jobz* = 'N', if *z* is omitted.

?hpev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

```
call chpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
call zhpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
call hpev(ap, w [,uplo] [,z] [,info])
```

?spevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

```
call sspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
call dspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
call spevd(ap, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as:

$$A = Z \Lambda Z^T.$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>ap, work</i>	<p>REAL for <i>sspevd</i></p> <p>DOUBLE PRECISION for <i>dspevd</i></p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be $\max(1, n*(n+1)/2)$</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p>

`if jobz = 'N', then $ldz \geq 1$;`
`if jobz = 'V', then $ldz \geq \max(1, n)$.`

lwork

INTEGER.

The dimension of the array *work*.

Constraints:

`if $n \leq 1$, then $lwork \geq 1$;`
`if jobz = 'N' and $n > 1$, then $lwork \geq 2*n$;`
`if jobz = 'V' and $n > 1$, then`
 `$lwork \geq n^2 + 6*n + 1$.`

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

`if $n \leq 1$, then $liwork \geq 1$;`
`if jobz = 'N' and $n > 1$, then $liwork \geq 1$;`
`if jobz = 'V' and $n > 1$, then $liwork \geq 5*n+3$.`

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w, *z*

REAL for `sspevd`
DOUBLE PRECISION for `dspevd`

Arrays:

w(*), size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

z(*ldz*,*).
The second dimension of *z* must be: at least 1 if *jobz* = 'N'; at least $\max(1, n)$ if *jobz* = 'V'.

If *jobz* = 'V', then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*. If *jobz* = 'N', then *z* is not referenced.

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> .
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required <i>liwork</i> .
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *spevd* interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p><i>jobz</i> = 'V', if <i>z</i> is present,</p> <p><i>jobz</i> = 'N', if <i>z</i> is omitted.</p>

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [hppevd](#).

See also [syevd](#) for matrices held in full storage, and [sbevd](#) for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax

```
call chpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

```
call zhpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

```
call hpevd(ap, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as: $A = Z\Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	COMPLEX for <i>chpevd</i> DOUBLE COMPLEX for <i>zhpevd</i> Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of Hermitian matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> .

Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;
 if $jobz = 'V'$, then $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

Constraints:

if $n \leq 1$, then $lwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;
 if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork

REAL for *chpevd*

DOUBLE PRECISION for *zhpevd*

Workspace array, its dimension $\max(1, lrwork)$.

lrwork

INTEGER.

The dimension of the array *rwork*. Constraints:

if $n \leq 1$, then $lrwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;
 if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>w</i>	<p>REAL for <code>chpevd</code></p> <p>DOUBLE PRECISION for <code>zhpevd</code></p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i>.</p>
<i>z</i>	<p>COMPLEX for <code>chpevd</code></p> <p>DOUBLE COMPLEX for <code>zhpevd</code></p> <p>Array, size (<i>ldz</i>, *).</p> <p>The second dimension of <i>z</i> must be:</p> <p>at least 1 if <i>jobz</i> = 'N';</p> <p>at least $\max(1, n)$ if <i>jobz</i> = 'V'.</p> <p>If <i>jobz</i> = 'V', then this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i>.</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>ap</i>	<p>On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i>.</p>
<i>work</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>work</i>(1) returns the required minimal size of <i>lwork</i>.</p>
<i>rwork</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>rwork</i>(1) returns the required minimal size of <i>lrwork</i>.</p>
<i>iwork</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>iwork</i>(1) returns the required minimal size of <i>liwork</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hpevd` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .

<code>z</code>	Holds the matrix Z of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: $jobz = 'V'$, if <code>z</code> is present, $jobz = 'N'$, if <code>z</code> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [spevd](#).

See also [heevd](#) for matrices held in full storage, and [hbevd](#) for banded matrices.

?spevx

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

```
call sspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)

call dspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)

call spevx(ap, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>job</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>ap, work</i>	<p>REAL for <i>sspevx</i></p> <p>DOUBLE PRECISION for <i>dspevx</i></p> <p>Arrays:</p> <p>Array <i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>work</i>(*) is a workspace array, size at least $\max(1, 8n)$.</p>
<i>vl, vu</i>	<p>REAL for <i>sspevx</i></p> <p>DOUBLE PRECISION for <i>dspevx</i></p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>REAL for <i>sspevx</i></p> <p>DOUBLE PRECISION for <i>dspevx</i></p> <p>The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.</p>

ldz INTEGER. The leading dimension of the output array *z*.

Constraints:

if *jobz* = 'N', then $ldz \geq 1$;

if *jobz* = 'V', then $ldz \geq \max(1, n)$.

iwork INTEGER. Workspace array, size at least $\max(1, 5n)$.

Output Parameters

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', $m = n$, if *range* = 'I', $m = iu - il + 1$, and if *range* = 'V' the exact value of *m* is not known in advance..

w, z REAL for *sspevx*
 DOUBLE PRECISION for *dspevx*

Arrays:
w(*), size at least $\max(1, n)$.
 If *info* = 0, contains the selected eigenvalues of the matrix *A* in ascending order.
z(*ldz*,*).
 The second dimension of *z* must be at least $\max(1, m)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If *jobz* = 'N', then *z* is not referenced.
 Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ifail INTEGER.

Array, size at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `spevx` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector with the number of elements n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to 2*?lamch('S').

?hpevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

```
call chpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
rwork, iwork, ifail, info)

call zhpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz, work,
rwork, iwork, ifail, info)

call hpevx(ap, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>job</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>ap, work</i>	<p>COMPLEX for chpevx</p> <p>DOUBLE COMPLEX for zhpevx</p> <p>Arrays:</p> <p>Array <i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p>

work(*) is a workspace array, size at least $\max(1, 2n)$.

vl, *vu*

REAL for *chpevx*

DOUBLE PRECISION for *zhpevx*

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu*

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for *chpevx*

DOUBLE PRECISION for *zhpevx*

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

INTEGER. The leading dimension of the output array *z*.

Constraints:

if *jobz* = 'N', then $ldz \geq 1$;

if *jobz* = 'V', then $ldz \geq \max(1, n)$.

rwork

REAL for *chpevx*

DOUBLE PRECISION for *zhpevx*

Workspace array, size at least $\max(1, 7n)$.

iwork

INTEGER. Workspace array, size at least $\max(1, 5n)$.

Output Parameters

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

m

INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

$0 \leq m \leq n$. If *range* = 'A', $m = n$, if *range* = 'I', $m = iu - il + 1$, and if *range* = 'V' the exact value of *m* is not known in advance..

w

REAL for *chpevx*

DOUBLE PRECISION for *zhpevx*

Array, size at least $\max(1, n)$.

If *info* = 0, contains the selected eigenvalues of the matrix *A* in ascending order.

z COMPLEX for *chpevx*
 DOUBLE COMPLEX for *zhpevx*
 Array *z(ldz,*)*.

The second dimension of *z* must be at least $\max(1, m)$.

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w(i)*.

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ifail INTEGER.

Array, size at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *hpevx* interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p>$jobz = 'V'$, if <i>z</i> is present,</p> <p>$jobz = 'N'$, if <i>z</i> is omitted</p> <p>Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows:</p> <p>$range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present,</p> <p>$range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present,</p> <p>$range = 'A'$, if none of <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> is present,</p> <p>Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.</p>

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \|T\|_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{lamch}('S')$.

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

```
call ssbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
call dsbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
call sbev(ab, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix *A*.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>A</i></p> <p>($kd \geq 0$).</p>
<i>ab, work</i>	<p>REAL for <i>ssbev</i></p> <p>DOUBLE PRECISION for <i>dsbev</i>.</p> <p>Arrays:</p> <p><i>ab(lda,*)</i> is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>work</i> (*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least $\max(1, 3n-2)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd + 1$.
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>if <i>jobz</i> = 'N', then $ldz \geq 1$;</p> <p>if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>

Output Parameters

<i>w, z</i>	<p>REAL for <i>ssbev</i></p> <p>DOUBLE PRECISION for <i>dsbev</i></p> <p>Arrays:</p> <p><i>w</i>(*), size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.</p> <p><i>z</i>(ldz,*).</p> <p>The second dimension of <i>z</i> must be at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix <i>A</i>, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>).</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
-------------	---

<i>ab</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form (see the description of ?sbtrd).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbeve` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hbev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

```
call chbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
call zhbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
call hbev(ab, w [,uplo] [,z] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix *A*.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed.
-------------	---

	<p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>kd</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).</p>
<i>ab, work</i>	<p>COMPLEX for chbev</p> <p>DOUBLE COMPLEX for zhbev.</p> <p>Arrays:</p> <p><i>ab(lda,*)</i> is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>work</i> (*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least $\max(1, n)$.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of <i>ab</i>; must be at least $kd + 1$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>if <i>jobz</i> = 'N', then $ldz \geq 1$;</p> <p>if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>rwork</i>	<p>REAL for chbev</p> <p>DOUBLE PRECISION for zhbev</p> <p>Workspace array, size at least $\max(1, 3n-2)$.</p>
Output Parameters	
<i>w</i>	<p>REAL for chbev</p> <p>DOUBLE PRECISION for zhbev</p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues in ascending order.</p>
<i>z</i>	<p>COMPLEX for chbev</p> <p>DOUBLE COMPLEX for zhbev.</p> <p>Array <i>z(ldz,*)</i>.</p> <p>The second dimension of <i>z</i> must be at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix <i>A</i>, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w(i)</i>.</p>

If `jobz = 'N'`, then `z` is not referenced.

`ab` On exit, this array is overwritten by the values generated during the reduction to tridiagonal form(see the description of [hbtrd](#)).

`info` INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the *i*th parameter had an illegal value.

If `info = i`, then the algorithm failed to converge;

i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hbevd` interface are the following:

`ab` Holds the array *A* of size $(kd+1, n)$.

`w` Holds the vector with the number of elements *n*.

`z` Holds the matrix *Z* of size (n, n) .

`uplo` Must be 'U' or 'L'. The default value is 'U'.

`jobz` Restored based on the presence of the argument `z` as follows:

`jobz = 'V'`, if `z` is present,

`jobz = 'N'`, if `z` is omitted.

?sbevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric band matrix using divide and conquer algorithm.

Syntax

```
call ssbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, iwork, liwork, info)
```

```
call dsbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, iwork, liwork, info)
```

```
call sbevd(ab, w [,uplo] [,z] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix *A*. In other words, it can compute the spectral factorization of *A* as:

$$A = Z \Lambda Z^T$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A * z_i = \lambda_i * z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>A</i></p> <p>($kd \geq 0$).</p>
<i>ab, work</i>	<p>REAL for <i>ssbevd</i></p> <p>DOUBLE PRECISION for <i>dsbevd</i>.</p> <p>Arrays:</p> <p><i>ab(lda,*)</i> is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd+1$.
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>if <i>jobz</i> = 'N', then $ldz \geq 1$;</p> <p>if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>if $n \leq 1$, then $lwork \geq 1$;</p> <p>if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq 2n$;</p> <p>if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq 2*n^2 + 5*n + 1$.</p>

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.

The dimension of the array *iwork*. Constraints: if $n \leq 1$, then $liwork < 1$; if $job = 'N'$ and $n > 1$, then $liwork < 1$; if $job = 'V'$ and $n > 1$, then $liwork < 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w, z REAL for *ssbevd*
DOUBLE PRECISION for *dsbevd*

Arrays:

$w(*)$, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

$z(ldz,*)$.

The second dimension of *z* must be:

at least 1 if $job = 'N'$;

at least $\max(1, n)$ if $job = 'V'$.

If $job = 'V'$, then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*. The *i*-th column of *Z* contains the eigenvector which corresponds to the eigenvalue $w(i)$.

If $job = 'N'$, then *z* is not referenced.

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

work(1) On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

iwork(1) On exit, if $liwork > 0$, then *iwork*(1) returns the required minimal size of *liwork*.

info INTEGER.

If $info = 0$, the execution is successful.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If *info* = -*i*, the *i*-th parameter had an illegal value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbevd` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If any of admissible *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [hbevd](#).

See also [syevd](#) for matrices held in full storage, and [spevd](#) for matrices held in packed storage.

?hbevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian band matrix using divide and conquer algorithm.

Syntax

```
call chbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)

call zhbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)
```

```
call hbevd(ab, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian band matrix A . In other words, it can compute the spectral factorization of A as: $A = Z*\Lambda*Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A*z_i = \lambda_i*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A.</p>
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	<p>INTEGER. The number of super- or sub-diagonals in A</p> <p>($kd \geq 0$).</p>
<i>ab, work</i>	<p>COMPLEX for chbevd</p> <p>DOUBLE COMPLEX for zhbevd.</p> <p>Arrays:</p> <p><i>ab</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>work</i> (*) is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd+1$.
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>if <i>jobz</i> = 'N', then $ldz \geq 1$;</p> <p>if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	INTEGER.

The dimension of the array *work*.

Constraints:

if $n \leq 1$, then $lwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n^2$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork

REAL for chbevd

DOUBLE PRECISION for zhbevd

Workspace array, size at least *lrwork*.

lrwork

INTEGER.

The dimension of the array *rwork*.

Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, size $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for chbevd

DOUBLE PRECISION for zhbevd

Array, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order.
See also *info*.

z	<p>COMPLEX for <code>chbevd</code> DOUBLE COMPLEX for <code>zhbevd</code> Array, size $(ldz,*)$. The second dimension of z must be: at least 1 if $jobz = 'N'$; at least $\max(1, n)$ if $jobz = 'V'$. If $jobz = 'V'$, then this array is overwritten by the unitary matrix Z which contains the eigenvectors of A. The i-th column of Z contains the eigenvector which corresponds to the eigenvalue $w(i)$. If $jobz = 'N'$, then z is not referenced.</p>
ab	<p>On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.</p>
$work(1)$	<p>On exit, if $lwork > 0$, then the real part of $work(1)$ returns the required minimal size of $lwork$.</p>
$rwork(1)$	<p>On exit, if $lrwork > 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.</p>
$iwork(1)$	<p>On exit, if $liwork > 0$, then $iwork(1)$ returns the required minimal size of $liwork$.</p>
$info$	<p>INTEGER. If $info = 0$, the execution is successful. If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If $info = -i$, the i-th parameter had an illegal value.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hbevd` interface are the following:

ab	Holds the array A of size $(kd+1, n)$.
w	Holds the vector with the number of elements n .
z	Holds the matrix Z of size (n, n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$jobz$	<p>Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present,</p>

$jobz = 'N'$, if z is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\varepsilon) \|A\|_2$, where ε is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [sbevd](#).

See also [heevd](#) for matrices held in full storage, and [hpevd](#) for matrices held in packed storage.

?sbevz

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

```
call ssbevz(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, iwork, ifail, info)

call dsbevz(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, iwork, ifail, info)

call sbevz(ab, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q] [,abstol]
[,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'.
	If <i>jobz</i> = 'N', then only eigenvalues are computed.
	If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.

<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices in range <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A.</p> <p>If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A.</p>
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	<p>INTEGER. The number of super- or sub-diagonals in A</p> <p>($kd \geq 0$).</p>
<i>ab, work</i>	<p>REAL for ssbevz</p> <p>DOUBLE PRECISION for dsbevz.</p> <p>Arrays:</p> <p>Arrays:</p> <p>Array <i>ab</i>(<i>lda</i>,*) contains either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>work</i> (*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least $\max(1, 7n)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd + 1$.
<i>vl, vu</i>	<p>REAL for ssbevz</p> <p>DOUBLE PRECISION for dsbevz.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>REAL for chpevx</p> <p>DOUBLE PRECISION for zhpevx</p>

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldq, ldz

INTEGER. The leading dimensions of the output arrays *q* and *z*, respectively.

Constraints:

$ldq \geq 1, ldz \geq 1;$

If *jobz* = 'V', then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$.

iwork

INTEGER. Workspace array, size at least $\max(1, 5n)$.

Output Parameters

q

REAL for ssbevxdouble PRECISION for dsbevxd.

Array, size (*ldz*,*n*).

If *jobz* = 'V', the *n*-by-*n* orthogonal matrix is used in the reduction to tridiagonal form.

If *jobz* = 'N', the array *q* is not referenced.

m

INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If *range* = 'A', *m* = *n*, if *range* = 'I', *m* = *iu-il*+1, and if *range* = 'V', the exact value of *m* is not known in advance.

w, z

REAL for ssbevxd.

DOUBLE PRECISION for dsbevxd.

Arrays:

w(*), size at least $\max(1, n)$. The first *m* elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.

z(*ldz*,*).

The second dimension of *z* must be at least $\max(1, m)$.

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If *uplo* = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix *T* are returned in rows *kd* and *kd*+1 of *ab*, and if *uplo* = 'L', the diagonal and first subdiagonal of *T* are returned in the first two rows of *ab*.

<i>ifail</i>	<p>INTEGER.</p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices the eigenvectors that failed to converge.</p> <p>If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = <i>i</i>, then <i>i</i> eigenvectors failed to converge; their indices are stored in the array <i>ifail</i>.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbevz` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p><i>jobz</i> = 'V', if <i>z</i> is present,</p> <p><i>jobz</i> = 'N', if <i>z</i> is omitted</p> <p>Note that there will be an error condition if either <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows:</p> <p><i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present,</p> <p><i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present,</p>

$range = 'A'$, if none of vl , vu , il , iu is present,

Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon \|T\|_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \lambda_{\text{mach}}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \lambda_{\text{mach}}('S')$.

?hbevz

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

```
call chbevz(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, rwork, iwork, ifail, info)
```

```
call zhbevz(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol, m, w,
z, ldz, work, rwork, iwork, ifail, info)
```

```
call hbevz(ab, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q] [,abstol]
[,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

	<p>If $uplo = 'U'$, ab stores the upper triangular part of A.</p> <p>If $uplo = 'L'$, ab stores the lower triangular part of A.</p>
n	INTEGER. The order of the matrix A ($n \geq 0$).
kd	<p>INTEGER. The number of super- or sub-diagonals in A</p> <p>($kd \geq 0$).</p>
$ab, work$	<p>COMPLEX for <code>chbev</code></p> <p>DOUBLE COMPLEX for <code>zhbev</code>.</p> <p>Arrays:</p> <p>$ab(lda,*)$ is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by $uplo$) in band storage format.</p> <p>The second dimension of ab must be at least $\max(1, n)$.</p> <p>$work(*)$ is a workspace array.</p> <p>The dimension of $work$ must be at least $\max(1, n)$.</p>
$ldab$	INTEGER. The leading dimension of ab ; must be at least $kd + 1$.
vl, vu	<p>REAL for <code>chbev</code></p> <p>DOUBLE PRECISION for <code>zhbev</code>.</p> <p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
il, iu	<p>INTEGER.</p> <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If $range = 'A'$ or $'V'$, il and iu are not referenced.</p>
$abstol$	<p>REAL for <code>chbev</code></p> <p>DOUBLE PRECISION for <code>zhbev</code>.</p> <p>The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.</p>
ldq, ldz	<p>INTEGER. The leading dimensions of the output arrays q and z, respectively.</p> <p>Constraints:</p> <p>$ldq \geq 1$, $ldz \geq 1$;</p> <p>If $jobz = 'V'$, then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$.</p>
$rwork$	<p>REAL for <code>chbev</code></p> <p>DOUBLE PRECISION for <code>zhbev</code></p>

Workspace array, size at least $\max(1, 7n)$.

iwork INTEGER. Workspace array, size at least $\max(1, 5n)$.

Output Parameters

q COMPLEX for `chbevxd` DOUBLE COMPLEX for `zhbevxd`.

Array, size (ldz, n) .

If `jobz` = 'V', the n -by- n unitary matrix is used in the reduction to tridiagonal form.

If `jobz` = 'N', the array *q* is not referenced.

m INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$.

If `range` = 'A', $m = n$, if `range` = 'I', $m = iu-il+1$, and if `range` = 'V', the exact value of *m* is not known in advance..

w REAL for `chbevxd`

DOUBLE PRECISION for `zhbevxd`

Array, size at least $\max(1, n)$. The first *m* elements contain the selected eigenvalues of the matrix *A* in ascending order.

z COMPLEX for `chbevxd`

DOUBLE COMPLEX for `zhbevxd`.

Array $z(ldz, *)$.

The second dimension of *z* must be at least $\max(1, m)$.

If `jobz` = 'V', then if `info` = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.

If `jobz` = 'N', then *z* is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if `range` = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If `uplo` = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix *T* are returned in rows *kd* and *kd*+1 of *ab*, and if `uplo` = 'L', the diagonal and first subdiagonal of *T* are returned in the first two rows of *ab*.

ifail INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hbevx` interface are the following:

<i>ab</i>	Holds the array A of size $(kd+1, n)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector with the number of elements n .
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	<p>Restored based on the presence of the argument z as follows:</p> <p>$jobz = 'V'$, if z is present,</p> <p>$jobz = 'N'$, if z is omitted</p> <p>Note that there will be an error condition if either $ifail$ or q is present and z is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments vl, vu, il, iu as follows:</p> <p>$range = 'V'$, if one of or both vl and vu are present,</p> <p>$range = 'I'$, if one of or both il and iu are present,</p> <p>$range = 'A'$, if none of vl, vu, il, iu is present,</p>

Note that there will be an error condition if one of or both *vl* and *vu* are present and at the same time one of or both *il* and *iu* are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{?lamch('S')}$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{?lamch('S')}$.

?stev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
call sstev(jobz, n, d, e, z, ldz, work, info)
call dstev(jobz, n, d, e, z, ldz, work, info)
call stev(d, e [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix *A*.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>d, e, work</i>	REAL for sstev DOUBLE PRECISION for dstev. Arrays: Array <i>d</i> (*) contains the <i>n</i> diagonal elements of the tridiagonal matrix <i>A</i> . The size of <i>d</i> must be at least max(1, <i>n</i>). Array <i>e</i> (*) contains the <i>n</i> -1 subdiagonal elements of the tridiagonal matrix <i>A</i> . The size of <i>e</i> must be at least max(1, <i>n</i>). The <i>n</i> -th element of this array is used as workspace. <i>work</i> (*) is a workspace array.

The dimension of *work* must be at least $\max(1, 2n-2)$.

If *jobz* = 'N', *work* is not referenced.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V' then $ldz \geq \max(1, n)$.

Output Parameters

d On exit, if *info* = 0, contains the eigenvalues of the matrix *A* in ascending order.

z REAL for *sstev*
DOUBLE PRECISION for *dstev*
Array, size (*ldz*,*).
The second dimension of *z* must be at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with the eigenvalue returned in *d*(*i*).
If *jobz* = 'N', then *z* is not referenced.

e On exit, this array is overwritten with intermediate results.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, then the algorithm failed to converge;
i elements of *e* did not converge to zero.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *stev* interface are the following:

d Holds the vector of length *n*.
e Holds the vector of length *n*.
z Holds the matrix *Z* of size (*n*, *n*).
jobz Restored based on the presence of the argument *z* as follows:
jobz = 'V', if *z* is present,
jobz = 'N', if *z* is omitted.

?stevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.

Syntax

```
call sstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call dstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call stevd(d, e [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization of T as: $T = Z^* \Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$T^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

There is no complex analogue of this routine.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>n</i>	<p>INTEGER. The order of the matrix T ($n \geq 0$).</p>
<i>d, e, work</i>	<p>REAL for sstevd</p> <p>DOUBLE PRECISION for dstevd.</p> <p>Arrays:</p> <p><i>d</i>(*) contains the n diagonal elements of the tridiagonal matrix T.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i>(*) contains the $n-1$ off-diagonal elements of T.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n)$. The n-th element of this array is used as workspace.</p> <p><i>work</i>(*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least <i>lwork</i>.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>. Constraints:</p> <p>$ldz \geq 1$ if <i>job</i> = 'N';</p> <p>$ldz \geq \max(1, n)$ if <i>job</i> = 'V'.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p>

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $lwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $lwork \geq n^2 + 4*n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

d

On exit, if $info = 0$, contains the eigenvalues of the matrix *T* in ascending order.

See also *info*.

z

REAL for *sstevd*

DOUBLE PRECISION for *dstevd*

Array, size (*ldz*,*) .

The second dimension of *z* must be:

at least 1 if $jobz = 'N'$;

at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *T*.

If $jobz = 'N'$, then *z* is not referenced.

e

On exit, this array is overwritten with intermediate results.

work(1)

On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

iwork(1)

On exit, if $liwork > 0$, then *iwork*(1) returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `stevd` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) .
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run, or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stevx

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
call sstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)
```

```
call dstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)
```

```
call stevx(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>job</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval: $vl < w(i) \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A ($n \geq 0$).</p>
<i>d, e, work</i>	<p>REAL for sstevx</p> <p>DOUBLE PRECISION for dstevx.</p> <p>Arrays:</p> <p><i>d</i>(*) contains the n diagonal elements of the tridiagonal matrix A.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i>(*) contains the $n-1$ subdiagonal elements of A.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n-1)$. The n-th element of this array is used as workspace.</p> <p><i>work</i>(*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least $\max(1, 5n)$.</p>
<i>vl, vu</i>	<p>REAL for sstevx</p> <p>DOUBLE PRECISION for dstevx.</p>

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: *vl* < *vu*.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for *sstevx*

DOUBLE PRECISION for *dstevx*. The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

INTEGER. The leading dimensions of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', then $ldz \geq \max(1, n)$.

iwork

INTEGER. Workspace array, size at least $\max(1, 5n)$.

Output Parameters

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$.

If *range* = 'A', $m = n$, if *range* = 'I', $m = iu - il + 1$, and if *range* = 'V' the exact value of *m* is unknown.

w, z

REAL for *sstevx*

DOUBLE PRECISION for *dstevx*.

Arrays:

w(*), size at least $\max(1, n)$.

The first *m* elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.

z(*ldz*,*) .

The second dimension of *z* must be at least $\max(1, m)$.

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

d, e

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

ifail

INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `stevx` interface are the following:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length n .
<i>w</i>	Holds the vector of length n .
<i>z</i>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector of length n .
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted Note that there will be an error condition if <i>ifail</i> is present and z is omitted.

range Restored based on the presence of arguments *vl*, *vu*, *il*, *iu* as follows:

range = 'V', if one of or both *vl* and *vu* are present,

range = 'I', if one of or both *il* and *iu* are present,

range = 'A', if none of *vl*, *vu*, *il*, *iu* is present,

Note that there will be an error condition if one of or both *vl* and *vu* are present and at the same time one of or both *il* and *iu* are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot |A|_1$ is used instead. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 \cdot \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 \cdot \text{lamch}('S')$.

?stevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

Syntax

```
call sstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call dstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz, work,
lwork, iwork, liwork, info)

call stevr(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stegr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L \cdot D \cdot L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T :

- Compute $T - \sigma_i = L_i \cdot D_i \cdot L_i^T$, such that $L_i \cdot D_i \cdot L_i^T$ is a relatively robust representation.
- Compute the eigenvalues, λ_j , of $L_i \cdot D_i \cdot L_i^T$ to high relative accuracy by the *dqds* algorithm.
- If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to Step (a).
- Given the approximate eigenvalue λ_j of $L_i \cdot D_i \cdot L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?stevr` calls `stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. `?stevr` calls `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w(i)$ in the half-open interval:</p> $vl < w(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> <p>For <i>range</i> = 'V' or 'I' and $iu - il < n - 1$, <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called.</p>
<i>n</i>	<p>INTEGER. The order of the matrix T ($n \geq 0$).</p>
<i>d, e, work</i>	<p>REAL for <code>sstevr</code></p> <p>DOUBLE PRECISION for <code>dstevr</code>.</p> <p>Arrays:</p> <p><i>d</i>(*) contains the <i>n</i> diagonal elements of the tridiagonal matrix T.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i>(*) contains the <i>n</i>-1 subdiagonal elements of A.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n-1)$. The <i>n</i>-th element of this array is used as workspace.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>vl, vu</i>	<p>REAL for <code>sstevr</code></p> <p>DOUBLE PRECISION for <code>dstevr</code>.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>REAL for <code>sstevr</code></p>

DOUBLE PRECISION for `dstevr`.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If `jobz = 'V'`, the eigenvalues and eigenvectors output have residual norms bounded by `abstol`, and the dot products between different eigenvectors are bounded by `abstol`. If `abstol < n * eps * ||T||`, then `n * eps * ||T||` will be used in its place, where `eps` is the machine precision, and `||T||` is the 1-norm of the matrix `T`. The eigenvalues are computed to an accuracy of `eps * ||T||` irrespective of `abstol`.

If high relative accuracy is important, set `abstol` to `?lamch('S')`.

`ldz`

INTEGER. The leading dimension of the output array `z`.

Constraints:

`ldz ≥ 1` if `jobz = 'N'`;

`ldz ≥ max(1, n)` if `jobz = 'V'`.

`lwork`

INTEGER.

The dimension of the array `work`. Constraint:

`lwork ≥ max(1, 20*n)`.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the required sizes of the `work` and `iwork` arrays, returns these values as the first entries of the `work` and `iwork` arrays, and no error message related to `lwork` or `liwork` is issued by [xerbla](#). See *Application Notes* for details.

`iwork`

INTEGER.

Workspace array, its dimension `max(1, liwork)`.

`liwork`

INTEGER.

The dimension of the array `iwork`,

`liwork ≥ max(1, 10*n)`.

If `liwork = -1`, then a workspace query is assumed; the routine only calculates the required sizes of the `work` and `iwork` arrays, returns these values as the first entries of the `work` and `iwork` arrays, and no error message related to `lwork` or `liwork` is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

`m`

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If `range = 'A'`, `m = n`, if `range = 'I'`, `m = iu-il+1`, and if `range = 'V'` the exact value of `m` is unknown..

`w, z`

REAL for `sstevr`

DOUBLE PRECISION for `dstevr`.

Arrays:

$w(*)$, size at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues of the matrix T in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

d, e

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

$isuppz$

INTEGER.

Array, size at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i-1)$ through $isuppz(2i)$.

Implemented only for $range = 'A'$ or $'I'$ and $iu-il = n-1$.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$iwork(1)$

On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, an internal error has occurred.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `stevr` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length n .
w	Holds the vector of length n .
z	Holds the matrix Z of size (n, n) , where the values n and m are significant.

<i>isuppz</i>	Holds the vector of length $(2*n)$, where the values $(2*m)$ are significant.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p>$jobz = 'V'$, if <i>z</i> is present,</p> <p>$jobz = 'N'$, if <i>z</i> is omitted</p> <p>Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows:</p> <p>$range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present,</p> <p>$range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present,</p> <p>$range = 'A'$, if none of <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> is present,</p> <p>Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.</p>

Application Notes

Normal execution of the routine `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems.

[Table "Driver Routines for Solving Nonsymmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Nonsymmetric Eigenproblems

Routine Name	Operation performed
gees	Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.
geesx	Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.
geev	Computes the eigenvalues and left and right eigenvectors of a general matrix.
geevx	Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

?gees

Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.

Syntax

```
call sgees(jobvs, sort, select, n, a, lda, sdim, wr, wi, vs, ldvs, work, lwork, bwork,
info)
call dgees(jobvs, sort, select, n, a, lda, sdim, wr, wi, vs, ldvs, work, lwork, bwork,
info)
call cgees(jobvs, sort, select, n, a, lda, sdim, w, vs, ldvs, work, lwork, rwork,
bwork, info)
call zgees(jobvs, sort, select, n, a, lda, sdim, w, vs, ldvs, work, lwork, rwork,
bwork, info)
call gees(a, wr, wi [,vs] [,select] [,sdim] [,info])
call gees(a, w [,vs] [,select] [,sdim] [,info])
```

Include Files

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ -c & a \end{bmatrix}$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm i\sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

<i>jobvs</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvs</i> = 'N', then Schur vectors are not computed.</p> <p>If <i>jobvs</i> = 'V', then Schur vectors are computed.</p>
<i>sort</i>	<p>CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).</p>
<i>select</i>	<p>LOGICAL FUNCTION of two REAL arguments for real flavors.</p> <p>LOGICAL FUNCTION of one COMPLEX argument for complex flavors.</p> <p><i>select</i> must be declared EXTERNAL in the calling subroutine.</p> <p>If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>select</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue $wr(j) + \sqrt{-1} * wi(j)$ is selected if <i>select</i>(<i>wr</i>(<i>j</i>), <i>wi</i>(<i>j</i>)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue <i>w</i>(<i>j</i>) is selected if <i>select</i>(<i>w</i>(<i>j</i>)) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>select</i>(<i>wr</i>(<i>j</i>), <i>wi</i>(<i>j</i>)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> may be set to <i>n</i>+2 (see <i>info</i> below).</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for sgees</p> <p>DOUBLE PRECISION for dgees</p> <p>COMPLEX for cgees</p> <p>DOUBLE COMPLEX for zgees.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i>.</p> <p>The second dimension of <i>a</i> must be at least max(1, <i>n</i>).</p> <p><i>work</i> is a workspace array, its dimension max(1, <i>lwork</i>).</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. Must be at least max(1, <i>n</i>).</p>
<i>ldvs</i>	<p>INTEGER. The leading dimension of the output array <i>vs</i>. Constraints:</p> <p><i>ldvs</i> ≥ 1;</p>

$ldvs \geq \max(1, n)$ if $jobvs = 'V'$.

lwork

INTEGER.

The dimension of the array *work*.

Constraint:

$lwork \geq \max(1, 3n)$ for real flavors;

$lwork \geq \max(1, 2n)$ for complex flavors.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for *cgees*

DOUBLE PRECISION for *zgees*

Workspace array, size at least $\max(1, n)$. Used in complex flavors only.

bwork

LOGICAL. Workspace array, size at least $\max(1, n)$. Not referenced if $sort = 'N'$.

Output Parameters

a

On exit, this array is overwritten by the real-Schur/Schur form *T*.

sdim

INTEGER.

If $sort = 'N'$, $sdim = 0$.

If $sort = 'S'$, $sdim$ is equal to the number of eigenvalues (after sorting) for which *select* is true.

Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

wr, wi

REAL for *sgees*

DOUBLE PRECISION for *dgees*

Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form *T*. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for *cgees*

DOUBLE COMPLEX for *zgees*.

Array, size at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form *T*.

vs

REAL for *sgees*

DOUBLE PRECISION for *dgees*

COMPLEX for *cgees*

DOUBLE COMPLEX for zgees.

Array *vs(ldvs,*)*; the second dimension of *vs* must be at least $\max(1, n)$.

If *jobvs* = 'V', *vs* contains the orthogonal/unitary matrix *Z* of Schur vectors.

If *jobvs* = 'N', *vs* is not referenced.

work(1)

On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$:

the QR algorithm failed to compute all the eigenvalues; elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged; if *jobvs* = 'V', *vs* contains the matrix which reduces *A* to its partially converged Schur form;

$i = n+1$:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

$i = n+2$:

after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy *select* = .TRUE.. This could also be caused by underflow due to scaling.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *gees* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>wr</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>wi</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>w</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>vs</i>	Holds the matrix <i>VS</i> of size (n, n) .
<i>jobvs</i>	Restored based on the presence of the argument <i>vs</i> as follows: <i>jobvs</i> = 'V', if <i>vs</i> is present, <i>jobvs</i> = 'N', if <i>vs</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows:

`sort = 'S'`, if *select* is present,
`sort = 'N'`, if *select* is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geesx

Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.

Syntax

```
call sgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs, rconde,
rcondv, work, lwork, iwork, liwork, bwork, info)

call dgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs, rconde,
rcondv, work, lwork, iwork, liwork, bwork, info)

call cgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde, rcondv,
work, lwork, rwork, bwork, info)

call zgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde, rcondv,
work, lwork, rwork, bwork, info)

call geesx(a, wr, wi [,vs] [,select] [,sdim] [,rconde] [,rcondv] [,info])

call geesx(a, w [,vs] [,select] [,sdim] [,rconde] [,rcondv] [,info])
```

Include Files

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real-Schur/Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (*rconde*); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (*rcondv*). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers *rconde* and *rcondv*, see [LUG], Section 4.10 (where these quantities are called *s* and *sep* respectively).

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm i\sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

<i>jobvs</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvs</i> = 'N', then Schur vectors are not computed.</p> <p>If <i>jobvs</i> = 'V', then Schur vectors are computed.</p>
<i>sort</i>	<p>CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).</p>
<i>select</i>	<p>LOGICAL FUNCTION of two REAL arguments for real flavors.</p> <p>LOGICAL FUNCTION of one COMPLEX argument for complex flavors.</p> <p><i>select</i> must be declared EXTERNAL in the calling subroutine.</p> <p>If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>select</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue $wr(j)+sqrt(-1)*wi(j)$ is selected if <i>select</i>(<i>wr</i>(<i>j</i>), <i>wi</i>(<i>j</i>)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue <i>w</i>(<i>j</i>) is selected if <i>select</i>(<i>w</i>(<i>j</i>)) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>select</i>(<i>wr</i>(<i>j</i>), <i>wi</i>(<i>j</i>))= .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> may be set to <i>n</i>+2 (see <i>info</i> below).</p>
<i>sense</i>	<p>CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for average of selected eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for selected right invariant subspace only;</p> <p>If <i>sense</i> = 'B', computed for both.</p> <p>If <i>sense</i> is 'E', 'V', or 'B', then <i>sort</i> must equal 'S'.</p>

n	INTEGER. The order of the matrix A ($n \geq 0$).
$a, work$	<p>REAL for sgeesx</p> <p>DOUBLE PRECISION for dgeesx</p> <p>COMPLEX for cgeesx</p> <p>DOUBLE COMPLEX for zgeesx.</p> <p>Arrays:</p> <p>$a(lda,*)$ is an array containing the n-by-n matrix A.</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>$work$ is a workspace array, its dimension $\max(1, lwork)$.</p>
lda	INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.
$ldvs$	<p>INTEGER. The leading dimension of the output array vs. Constraints:</p> <p>$ldvs \geq 1$;</p> <p>$ldvs \geq \max(1, n)$ if $jobvs = 'V'$.</p>
$lwork$	<p>INTEGER.</p> <p>The dimension of the array $work$. Constraint:</p> <p>$lwork \geq \max(1, 3n)$ for real flavors;</p> <p>$lwork \geq \max(1, 2n)$ for complex flavors.</p> <p>Also, if $sense = 'E', 'V',$ or $'B'$, then</p> <p>$lwork \geq n+2*sdim*(n-sdim)$ for real flavors;</p> <p>$lwork \geq 2*sdim*(n-sdim)$ for complex flavors;</p> <p>where $sdim$ is the number of selected eigenvalues computed by this routine.</p> <p>Note that $2*sdim*(n-sdim) \leq n*n/2$. Note also that an error is only returned if $lwork < \max(1, 2*n)$, but if $sense = 'E',$ or $'V',$ or $'B'$ this may not be large enough.</p> <p>For good performance, $lwork$ must generally be larger.</p> <p>If $lwork = -1$, then a workspace query is assumed; the routine only calculates upper bound on the optimal size of the array $work$, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.</p>
$iwork$	<p>INTEGER.</p> <p>Workspace array, size ($liwork$). Used in real flavors only. Not referenced if $sense = 'N'$ or $'E'$.</p>
$liwork$	<p>INTEGER.</p> <p>The dimension of the array $iwork$. Used in real flavors only.</p> <p>Constraint:</p> <p>$liwork \geq 1$;</p>

if *sense* = 'V' or 'B', $liwork \geq sdim * (n - sdim)$.

rwork

REAL for *cgeesx*

DOUBLE PRECISION for *zgeesx*

Workspace array, size at least $\max(1, n)$. Used in complex flavors only.

bwork

LOGICAL. Workspace array, size at least $\max(1, n)$. Not referenced if *sort* = 'N'.

Output Parameters

a

On exit, this array is overwritten by the real-Schur/Schur form *T*.

sdim

INTEGER.

If *sort* = 'N', *sdim* = 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *select* is true.

Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

wr, wi

REAL for *sgeesx*

DOUBLE PRECISION for *dgeesx*

Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form *T*. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for *cgeesx*

DOUBLE COMPLEX for *zgeesx*.

Array, size at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form *T*.

vs

REAL for *sgeesx*

DOUBLE PRECISION for *dgeesx*

COMPLEX for *cgeesx*

DOUBLE COMPLEX for *zgeesx*.

Array *vs(ldvs,*)*; the second dimension of *vs* must be at least $\max(1, n)$.

If *jobvs* = 'V', *vs* contains the orthogonal/unitary matrix *Z* of Schur vectors.

If *jobvs* = 'N', *vs* is not referenced.

rconde, rcondv

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

If *sense* = 'E' or 'B', *rconde* contains the reciprocal condition number for the average of the selected eigenvalues.

If *sense* = 'N' or 'V', *rconde* is not referenced.

If *sense* = 'V' or 'B', *rcondv* contains the reciprocal condition number for the selected right invariant subspace.

If *sense* = 'N' or 'E', *rcondv* is not referenced.

work(1)

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, and

i ≤ *n*:

the QR algorithm failed to compute all the eigenvalues; elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged; if *jobvs* = 'V', *vs* contains the transformation which reduces *A* to its partially converged Schur form;

i = *n*+1:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

i = *n*+2:

after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy *select* = .TRUE.. This could also be caused by underflow due to scaling.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *geesx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>wr</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>wi</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>w</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>vs</i>	Holds the matrix <i>VS</i> of size (<i>n</i> , <i>n</i>).
<i>jobvs</i>	Restored based on the presence of the argument <i>vs</i> as follows: <i>jobvs</i> = 'V', if <i>vs</i> is present, <i>jobvs</i> = 'N', if <i>vs</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present,

`sort = 'N'`, if `select` is omitted.

`sense`

Restored based on the presence of arguments `rconde` and `rcondv` as follows:

`sense = 'B'`, if both `rconde` and `rcondv` are present,

`sense = 'E'`, if `rconde` is present and `rcondv` omitted,

`sense = 'V'`, if `rconde` is omitted and `rcondv` present,

`sense = 'N'`, if both `rconde` and `rcondv` are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If you choose the first option and set any of admissible `lwork` (or `liwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`) on exit. Use this value (`work(1)`, `iwork(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geev

Computes the eigenvalues and left and right eigenvectors of a general matrix.

Syntax

```
call sgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork, info)
call dgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork, info)
call cgeev(jobvl, jobvr, n, a, lda, w, vl, ldvl, vr, ldvr, work, lwork, rwork, info)
call zgeev(jobvl, jobvr, n, a, lda, w, vl, ldvl, vr, ldvr, work, lwork, rwork, info)
call geev(a, wr, wi [,vl] [,vr] [,info])
call geev(a, w [,vl] [,vr] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors. The right eigenvector v of A satisfies

$$A * v = \lambda * v$$

where λ is its eigenvalue.

The left eigenvector u of A satisfies

$$u^H * A = \lambda * u^H$$

where u^H denotes the conjugate transpose of u . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Input Parameters

<i>jobvl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', then left eigenvectors of <i>A</i> are not computed.</p> <p>If <i>jobvl</i> = 'V', then left eigenvectors of <i>A</i> are computed.</p>
<i>jobvr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', then right eigenvectors of <i>A</i> are not computed.</p> <p>If <i>jobvr</i> = 'V', then right eigenvectors of <i>A</i> are computed.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for <i>sggev</i></p> <p>DOUBLE PRECISION for <i>dgeev</i></p> <p>COMPLEX for <i>cgeev</i></p> <p>DOUBLE COMPLEX for <i>zgeev</i>.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. Must be at least $\max(1, n)$.</p>
<i>ldvl, ldvr</i>	<p>INTEGER. The leading dimensions of the output arrays <i>vl</i> and <i>vr</i>, respectively.</p> <p>Constraints:</p> <p>$ldvl \geq 1; ldvr \geq 1$.</p> <p>If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$;</p> <p>If <i>jobvr</i> = 'V', $ldvr \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraint for real flavors: $lwork \geq \max(1, 3n)$. If computing eigenvectors (<i>jobvl</i> = 'V' or <i>jobvr</i> = 'V'), $lwork \geq \max(1, 4n)$.</p> <p>Constraint for complex flavors: $lwork \geq \max(1, 2n)$.</p> <p>For good performance, <i>lwork</i> must generally be larger.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p>

rwork REAL for cgeev
DOUBLE PRECISION for zgeev
Workspace array, size at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

a On exit, this array is overwritten.

wr, wi REAL for sgeev
DOUBLE PRECISION for dgeev
Arrays, size at least $\max(1, n)$ each.
Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w COMPLEX for cgeev
DOUBLE COMPLEX for zgeev.
Array, size at least $\max(1, n)$.
Contains the computed eigenvalues.

vl, vr REAL for sgeev
DOUBLE PRECISION for dgeev
COMPLEX for cgeev
DOUBLE COMPLEX for zgeev.
Arrays:
vl(ldvl,)*; the second dimension of *vl* must be at least $\max(1, n)$.
If *jobvl* = 'N', *vl* is not referenced.
For real flavors:
If the *j*-th eigenvalue is real, then $u_j = vl(:, j)$, the *j*-th column of *vl*.
If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then for $i = \sqrt{-1}$, $u_j = vl(:, j) + i*vl(:, j+1)$ and $u_{j+1} = vl(:, j) - i*vl(:, j+1)$.
For complex flavors:
 $u_j = vl(:, j)$, the *j*-th column of *vl*.
vr(ldvr,)*; the second dimension of *vr* must be at least $\max(1, n)$.
If *jobvr* = 'N', *vr* is not referenced.
For real flavors:
If the *j*-th eigenvalue is real, then $v_j = vr(:, j)$, the *j*-th column of *vr*.
If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then for $i = \sqrt{-1}$, $v_j = vr(:, j) + i*vr(:, j+1)$ and $v_{j+1} = vr(:, j) - i*vr(:, j+1)$.
For complex flavors:

$v_j = vr(:, j)$, the j -th column of vr .

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:n$ of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *geev* interface are the following:

a Holds the matrix *A* of size (n, n) .

wr Holds the vector of length n . Used in real flavors only.

wi Holds the vector of length n . Used in real flavors only.

w Holds the vector of length n . Used in complex flavors only.

vl Holds the matrix *VL* of size (n, n) .

vr Holds the matrix *VR* of size (n, n) .

jobvl Restored based on the presence of the argument *vl* as follows:
jobvl = 'V', if *vl* is present,
jobvl = 'N', if *vl* is omitted.

jobvr Restored based on the presence of the argument *vr* as follows:
jobvr = 'V', if *vr* is present,
jobvr = 'N', if *vr* is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine exits immediately with an error and does not provide any information on the recommended workspace.

?geevx

Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

Syntax

```
call sgeevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, ilo,
ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)
```

```
call dgeevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, ilo,
ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)
```

```
call cgeevx(balanc, jobvl, jobvr, sense, n, a, lda, w, vl, ldvl, vr, ldvr, ilo, ihi,
scale, abnrm, rconde, rcondv, work, lwork, rwork, info)
```

```
call zgeevx(balanc, jobvl, jobvr, sense, n, a, lda, w, vl, ldvl, vr, ldvr, ilo, ihi,
scale, abnrm, rconde, rcondv, work, lwork, rwork, info)
```

```
call geevx(a, wr, wi [,vl] [,vr] [,balanc] [,ilo] [,ihi] [,scale] [,abnrm] [, rconde]
[,rcondv] [,info])
```

```
call geevx(a, w [,vl] [,vr] [,balanc] [,ilo] [,ihi] [,scale] [,abnrm] [,rconde] [,
rcondv] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *scale*, and *abnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

The right eigenvector v of A satisfies

$$A \cdot v = \lambda \cdot v$$

where λ is its eigenvalue.

The left eigenvector u of A satisfies

$$u^H A = \lambda u^H$$

where u^H denotes the conjugate transpose of u . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D \cdot A \cdot \text{inv}(D)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

Input Parameters

<i>balanc</i>	<p>CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;</p> <p>If <i>balanc</i> = 'S', diagonally scale the matrix, i.e. replace <i>A</i> by $D*A*inv(D)$, where <i>D</i> is a diagonal matrix chosen to make the rows and columns of <i>A</i> more equal in norm. Do not permute;</p> <p>If <i>balanc</i> = 'B', both diagonally scale and permute <i>A</i>.</p> <p>Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<i>jobvl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', left eigenvectors of <i>A</i> are not computed;</p> <p>If <i>jobvl</i> = 'V', left eigenvectors of <i>A</i> are computed.</p> <p>If <i>sense</i> = 'E' or 'B', then <i>jobvl</i> must be 'V'.</p>
<i>jobvr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', right eigenvectors of <i>A</i> are not computed;</p> <p>If <i>jobvr</i> = 'V', right eigenvectors of <i>A</i> are computed.</p> <p>If <i>sense</i> = 'E' or 'B', then <i>jobvr</i> must be 'V'.</p>
<i>sense</i>	<p>CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for right eigenvectors only;</p> <p>If <i>sense</i> = 'B', computed for eigenvalues and right eigenvectors.</p> <p>If <i>sense</i> is 'E' or 'B', both left and right eigenvectors must also be computed (<i>jobvl</i> = 'V' and <i>jobvr</i> = 'V').</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for <i>sgeevx</i></p> <p>DOUBLE PRECISION for <i>dgeevx</i></p> <p>COMPLEX for <i>cgeevx</i></p> <p>DOUBLE COMPLEX for <i>zgeevx</i>.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>

	<i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>ldvl, ldvr</i>	<p>INTEGER. The leading dimensions of the output arrays <i>vl</i> and <i>vr</i>, respectively.</p> <p>Constraints:</p> <p>$ldvl \geq 1; ldvr \geq 1$.</p> <p>If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$;</p> <p>If <i>jobvr</i> = 'V', $ldvr \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p><i>For real flavors:</i></p> <p>If <i>sense</i> = 'N' or 'E', $lwork \geq \max(1, 2n)$, and if <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V', $lwork \geq 3n$;</p> <p>If <i>sense</i> = 'V' or 'B', $lwork \geq n*(n+6)$.</p> <p>For good performance, <i>lwork</i> must generally be larger.</p> <p><i>For complex flavors:</i></p> <p>If <i>sense</i> = 'N' or 'E', $lwork \geq \max(1, 2n)$;</p> <p>If <i>sense</i> = 'V' or 'B', $lwork \geq n^2 + 2n$. For good performance, <i>lwork</i> must generally be larger.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p>
<i>rwork</i>	<p>REAL for <i>cgeevx</i></p> <p>DOUBLE PRECISION for <i>zgeevx</i></p> <p>Workspace array, size at least $\max(1, 2n)$. Used in complex flavors only.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, size at least $\max(1, 2n-2)$. Used in real flavors only. Not referenced if <i>sense</i> = 'N' or 'E'.</p>

Output Parameters

<i>a</i>	<p>On exit, this array is overwritten.</p> <p>If <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V', it contains the real-Schur/Schur form of the balanced version of the input matrix <i>A</i>.</p>
<i>wr, wi</i>	<p>REAL for <i>sgeevx</i></p> <p>DOUBLE PRECISION for <i>dgeevx</i></p>

Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for *cgeevx*

DOUBLE COMPLEX for *zgeevx*.

Array, size at least $\max(1, n)$. Contains the computed eigenvalues.

vl, vr

REAL for *sgeevx*

DOUBLE PRECISION for *dgeevx*

COMPLEX for *cgeevx*

DOUBLE COMPLEX for *zgeevx*.

Arrays:

vl(ldvl,)*; the second dimension of *vl* must be at least $\max(1, n)$.

If *jobvl* = 'N', *vl* is not referenced.

For real flavors:

If the *j*-th eigenvalue is real, then $u_j = vl(:, j)$, the *j*-th column of *vl*.

If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, $u_j = vl(:, j) + i*vl(:, j+1)$ and $u_{j+1} = vl(:, j) - i*vl(:, j+1)$.

For complex flavors:

$u_j = vl(:, j)$, the *j*-th column of *vl*.

vr(ldvr,)*; the second dimension of *vr* must be at least $\max(1, n)$.

If *jobvr* = 'N', *vr* is not referenced.

For real flavors:

If the *j*-th eigenvalue is real, then $v_j = vr(:, j)$, the *j*-th column of *vr*.

If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, $v_j = vr(:, j) + i*vr(:, j+1)$ and $v_{j+1} = vr(:, j) - i*vr(:, j+1)$.

For complex flavors:

$v_j = vr(:, j)$, the *j*-th column of *vr*.

ilo, ihi

INTEGER. *ilo* and *ihi* are integer values determined when *A* was balanced.

The balanced $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If *balanc* = 'N' or 'S', *ilo* = 1 and *ihi* = *n*.

scale

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, size at least $\max(1, n)$. Details of the permutations and scaling factors applied when balancing *A*.

If $P(j)$ is the index of the row and column interchanged with row and column j , and $D(j)$ is the scaling factor applied to row and column j , then

$scale(j) = P(j)$, for $j = 1, \dots, ilo-1$
 $= D(j)$, for $j = ilo, \dots, ihi$
 $= P(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

rconde, rcondv

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Arrays, size at least $\max(1, n)$ each.

rconde(j) is the reciprocal condition number of the j -th eigenvalue.

rcondv(j) is the reciprocal condition number of the j -th right eigenvector.

work(1)

On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i th parameter had an illegal value.

If *info* = i , the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:*ilo*-1 and $i+1:n$ of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain eigenvalues which have converged.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *geevx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>wr</i>	Holds the vector of length n . Used in real flavors only.
<i>wi</i>	Holds the vector of length n . Used in real flavors only.
<i>w</i>	Holds the vector of length n . Used in complex flavors only.
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, n) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, n) .
<i>scale</i>	Holds the vector of length n .

<i>rconde</i>	Holds the vector of length <i>n</i> .
<i>rcondv</i>	Holds the vector of length <i>n</i> .
<i>balanc</i>	Must be 'N', 'B', 'P' or 'S'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Singular Value Decomposition - LAPACK Driver Routines

Table "Driver Routines for Singular Value Decomposition" lists the LAPACK driver routines that perform singular value decomposition for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are the same except that the first character is removed.

Driver Routines for Singular Value Decomposition

Routine Name	Operation performed
?gesvd	Computes the singular value decomposition of a general rectangular matrix.
?gesdd	Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.
?gejsv	Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method.
?gesvj	Computes the singular value decomposition of a real matrix using Jacobi plane rotations.

Routine Name	Operation performed
?ggsvd	Computes the generalized singular value decomposition of a pair of general rectangular matrices.

Singular Value Decomposition - LAPACK Computational Routines

[?gesvd](#)

Computes the singular value decomposition of a general rectangular matrix.

Syntax

```
call sgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, info)
call dgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, info)
call cgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, info)
call zgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, info)
call gesvd(a, s [,u] [,vt] [,ww] [,job] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written as

$A = U \Sigma V^T$ for real routines

$A = U \Sigma V^H$ for complex routines

where Σ is an m -by- n matrix which is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns V^T (for real flavors) or V^H (for complex flavors), not V .

Input Parameters

jobu CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix U .

If *jobu* = 'A', all m columns of U are returned in the array *u*;

if *jobu* = 'S', the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the array *u*;

if *jobu* = 'O', the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the array *a*;

if *jobu* = 'N', no columns of U (no left singular vectors) are computed.

jobvt CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix V^T/V^H .

If *jobvt* = 'A', all n rows of V^T/V^H are returned in the array *vt*;

if $jobvt = 'S'$, the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are returned in the array vt ;
 if $jobvt = 'O'$, the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are overwritten on the array a ;
 if $jobvt = 'N'$, no rows of V^T/V^H (no right singular vectors) are computed.
 $jobvt$ and $jobu$ cannot both be $'O'$.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for `sge`svd
 DOUBLE PRECISION for `dge`svd
 COMPLEX for `cge`svd
 DOUBLE COMPLEX for `zge`svd.

Arrays:

$a(lda,*)$ is an array containing the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of the array a .

Must be at least $\max(1, m)$.

$ldu, ldvt$ INTEGER. The leading dimensions of the output arrays u and vt , respectively.

Constraints:

$ldu \geq 1$; $ldvt \geq 1$.

If $jobu = 'A'$ or $'S'$, $ldu \geq m$;

If $jobvt = 'A'$, $ldvt \geq n$;

If $jobvt = 'S'$, $ldvt \geq \min(m, n)$.

$lwork$ INTEGER.

The dimension of the array $work$.

Constraints:

$lwork \geq 1$

$lwork \geq \max(3 \cdot \min(m, n) + \max(m, n), 5 \cdot \min(m, n))$ (for real flavors);

$lwork \geq 2 \cdot \min(m, n) + \max(m, n)$ (for complex flavors).

For good performance, $lwork$ must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for details.

$rwork$ REAL for `cge`svd

DOUBLE PRECISION for zgesvd

Workspace array, size at least $\max(1, 5 \cdot \min(m, n))$. Used in complex flavors only.

Output Parameters

a

On exit,

If *jobu* = 'O', *a* is overwritten with the first $\min(m, n)$ columns of *U* (the left singular vectors stored columnwise);

If *jobvt* = 'O', *a* is overwritten with the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored rowwise);

If *jobu* ≠ 'O' and *jobvt* ≠ 'O', the contents of *a* are destroyed.

s

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, size at least $\max(1, \min(m, n))$. Contains the singular values of *A* sorted so that $s(i) \geq s(i+1)$.

u, vt

REAL for sgesvd

DOUBLE PRECISION for dgesvd

COMPLEX for cgesvd

DOUBLE COMPLEX for zgesvd.

Arrays:

u(ldu,)*; the second dimension of *u* must be at least $\max(1, m)$ if *jobu* = 'A', and at least $\max(1, \min(m, n))$ if *jobu* = 'S'.

If *jobu* = 'A', *u* contains the *m*-by-*m* orthogonal/unitary matrix *U*.

If *jobu* = 'S', *u* contains the first $\min(m, n)$ columns of *U* (the left singular vectors stored column-wise).

If *jobu* = 'N' or 'O', *u* is not referenced.

vt(ldvt,)*; the second dimension of *vt* must be at least $\max(1, n)$.

If *jobvt* = 'A', *vt* contains the *n*-by-*n* orthogonal/unitary matrix V^T/V^H .

If *jobvt* = 'S', *vt* contains the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored row-wise).

If *jobvt* = 'N' or 'O', *vt* is not referenced.

work

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

For real flavors:

If *info* > 0, *work*(2: $\min(m, n)$) contains the unconverged superdiagonal elements of an upper bidiagonal matrix *B* whose diagonal is in *s* (not necessarily sorted). *B* satisfies $A = u * B * vt$, so it has the same singular values as *A*, and singular vectors related by *u* and *vt*.

<i>rwork</i>	On exit (for complex flavors), if <i>info</i> > 0, <i>rwork</i> (1:min(<i>m</i> , <i>n</i>)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix <i>B</i> whose diagonal is in <i>s</i> (not necessarily sorted). <i>B</i> satisfies $A = U^*B^*VT$, so it has the same singular values as <i>A</i> , and singular vectors related by <i>u</i> and <i>vt</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then if ?bdsqr did not converge, <i>i</i> specifies how many superdiagonals of the intermediate bidiagonal form <i>B</i> did not converge to zero (see the description of the <i>work</i> and <i>rwork</i> parameters for details).

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *gesvd* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>s</i>	Holds the vector of length min(<i>m</i> , <i>n</i>).
<i>u</i>	If present and is a square <i>m</i> -by- <i>m</i> matrix, on exit contains the <i>m</i> -by- <i>m</i> orthogonal/unitary matrix <i>U</i> . Otherwise, if present, on exit contains the first min(<i>m</i> , <i>n</i>) columns of the matrix <i>U</i> (left singular vectors stored column-wise).
<i>vt</i>	If present and is a square <i>n</i> -by- <i>n</i> matrix, on exit contains the <i>n</i> -by- <i>n</i> orthogonal/unitary matrix V^T/V^H . Otherwise, if present, on exit contains the first min(<i>m</i> , <i>n</i>) rows of the matrix V^T/V^H (right singular vectors stored row-wise).
<i>ww</i>	Holds the vector of length min(<i>m</i> , <i>n</i>)-1. <i>ww</i> contains the unconverged superdiagonal elements of an upper bidiagonal matrix <i>B</i> whose diagonal is in <i>s</i> (not necessarily sorted). <i>B</i> satisfies $A = U^*B^*VT$, so it has the same singular values as <i>A</i> , and singular vectors related by <i>U</i> and <i>VT</i> .
<i>job</i>	Must be either 'N', or 'U', or 'V'. The default value is 'N'. If <i>job</i> = 'U', and <i>u</i> is not present, then <i>u</i> is returned in the array <i>a</i> . If <i>job</i> = 'V', and <i>vt</i> is not present, then <i>vt</i> is returned in the array <i>a</i> .

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gesdd

Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.

Syntax

```
call sgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)
call dgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)
call cgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, iwork, info)
call zgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, iwork, info)
call gesdd(a, s [,u] [,vt] [,jobz] [,info])
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors.

If singular vectors are desired, it uses a divide-and-conquer algorithm. The SVD is written

$A = U \Sigma V^T$ for real routines,

$A = U \Sigma V^H$ for complex routines,

where Σ is an m -by- n matrix which is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns $vt = V^T$ (for real flavors) or $vt = V^H$ (for complex flavors), not V .

Input Parameters

`jobz` CHARACTER*1. Must be 'A', 'S', 'O', or 'N'.
Specifies options for computing all or part of the matrices U and V .
If `jobz` = 'A', all m columns of U and all n rows of V^T or V^H are returned in the arrays `u` and `vt`;
if `jobz` = 'S', the first $\min(m, n)$ columns of U and the first $\min(m, n)$ rows of V^T or V^H are returned in the arrays `u` and `vt`;
if `jobz` = 'O', then
if $m \geq n$, the first n columns of U are overwritten in the array `a` and all rows of V^T or V^H are returned in the array `vt`;
if $m < n$, all columns of U are returned in the array `u` and the first m rows of V^T or V^H are overwritten in the array `a`;

if $jobz = 'N'$, no columns of U or rows of V^T or V^H are computed.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgesdd
DOUBLE PRECISION for dgesdd
COMPLEX for cgesdd
DOUBLE COMPLEX for zgesdd.

Arrays:

$a(lda,*)$ is an array containing the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of the array a . Must be at least $\max(1, m)$.

$ldu, ldvt$ INTEGER. The leading dimensions of the output arrays u and vt , respectively.

Constraints:

$ldu \geq 1; ldvt \geq 1$.

If $jobz = 'S'$ or $'A'$, or $jobz = 'O'$ and $m < n$,

then $ldu \geq m$;

If $jobz = 'A'$ or $jobz = 'O'$ and $m \geq n$,

then $ldvt \geq n$;

If $jobz = 'S'$, $ldvt \geq \min(m, n)$.

$lwork$ INTEGER.

The dimension of the array $work$; $lwork \geq 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the $work(1)$, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the theoretical minimum value of $lwork$ when a workspace query is not performed.

$rwork$ REAL for cgesdd
DOUBLE PRECISION for zgesdd

Workspace array, size at least $\max(1, 7 * \min(m, n))$ if $jobz = 'N'$.

Otherwise, the dimension of $rwork$ must be at least

$\max(1, \min(m, n) * \max(5 * \min(m, n) + 7, 2 * \max(m, n) + 2 * \min(m, n) + 1))$.

This array is used in complex flavors only.

$iwork$ INTEGER. Workspace array, size at least $\max(1, 8 * \min(m, n))$.

Output Parameters

<i>a</i>	<p>On exit:</p> <p>If <i>jobz</i> = 'O', then if $m \geq n$, <i>a</i> is overwritten with the first <i>n</i> columns of <i>U</i> (the left singular vectors, stored columnwise). If $m < n$, <i>a</i> is overwritten with the first <i>m</i> rows of V^T (the right singular vectors, stored rowwise);</p> <p>If <i>jobz</i> ≠ 'O', the contents of <i>a</i> are destroyed.</p>
<i>s</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p> <p>Array, size at least $\max(1, \min(m, n))$. Contains the singular values of <i>A</i> sorted so that $s(i) \geq s(i+1)$.</p>
<i>u, vt</i>	<p>REAL for sgesdd</p> <p>DOUBLE PRECISION for dgesdd</p> <p>COMPLEX for cgesdd</p> <p>DOUBLE COMPLEX for zgesdd.</p> <p>Arrays:</p> <p><i>u</i>(<i>ldu</i>,*); the second dimension of <i>u</i> must be at least $\max(1, m)$ if <i>jobz</i> = 'A' or <i>jobz</i> = 'O' and $m < n$.</p> <p>If <i>jobz</i> = 'S', the second dimension of <i>u</i> must be at least $\max(1, \min(m, n))$.</p> <p>If <i>jobz</i> = 'A' or <i>jobz</i> = 'O' and $m < n$, <i>u</i> contains the <i>m</i>-by-<i>m</i> orthogonal/unitary matrix <i>U</i>.</p> <p>If <i>jobz</i> = 'S', <i>u</i> contains the first $\min(m, n)$ columns of <i>U</i> (the left singular vectors, stored columnwise).</p> <p>If <i>jobz</i> = 'O' and $m \geq n$, or <i>jobz</i> = 'N', <i>u</i> is not referenced.</p> <p><i>vt</i>(<i>ldvt</i>,*); the second dimension of <i>vt</i> must be at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'A' or <i>jobz</i> = 'O' and $m \geq n$, <i>vt</i> contains the <i>n</i>-by-<i>n</i> orthogonal/unitary matrix V^T.</p> <p>If <i>jobz</i> = 'S', <i>vt</i> contains the first $\min(m, n)$ rows of V^T (the right singular vectors, stored rowwise).</p> <p>If <i>jobz</i> = 'O' and $m < n$, or <i>jobz</i> = 'N', <i>vt</i> is not referenced.</p>
<i>work</i> (<i>l</i>)	<p>On exit, if <i>info</i> = 0, then <i>work</i>(<i>l</i>) returns the optimal size of <i>lwork</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = <i>i</i>, then ?bdsdc did not converge, updating process failed.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gesdd` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>s</code>	Holds the vector of length $\min(m, n)$.
<code>u</code>	Holds the matrix U of size <ul style="list-style-type: none"> (m, m) if <code>jobz</code> = 'A' or <code>jobz</code> = 'O' and $m < n$ $(m, \min(m, n))$ if <code>jobz</code> = 'S' <code>u</code> is not referenced if <code>jobz</code> is not supplied or if <code>jobz</code> = 'N' or <code>jobz</code> = 'O' and $m \geq n$.
<code>vt</code>	Holds the matrix VT of size <ul style="list-style-type: none"> (n, n) if <code>jobz</code> = 'A' or <code>jobz</code> = 'O' and $m \geq n$ $(\min(m, n), n)$ if <code>jobz</code> = 'S' <code>vt</code> is not referenced if <code>jobz</code> is not supplied or if <code>jobz</code> = 'N' or <code>jobz</code> = 'O' and $m < n$.
<code>job</code>	Must be 'N', 'A', 'S', or 'O'. The default value is 'N'.

Application Notes

The theoretical minimum value for `lwork` depends on the flavor of the routine.

For real flavors:

If `jobz` = 'N', `lwork` = $3 \cdot \min(m, n) + \max(\max(m, n), 6 \cdot \min(m, n))$;

If `jobz` = 'O', `lwork` = $3 \cdot (\min(m, n))^2 + \max(\max(m, n), 5 \cdot (\min(m, n))^2 + 4 \cdot \min(m, n))$;

If `jobz` = 'S' or 'A', `lwork` = $\min(m, n) \cdot (6 + 4 \cdot \min(m, n)) + \max(m, n)$;

For complex flavors:

If `jobz` = 'N', `lwork` = $2 \cdot \min(m, n) + \max(m, n)$;

If `jobz` = 'O', `lwork` = $2 \cdot (\min(m, n))^2 + \max(m, n) + 2 \cdot \min(m, n)$;

If `jobz` = 'S' or 'A', `lwork` = $(\min(m, n))^2 + \max(m, n) + 2 \cdot \min(m, n)$;

The optimal value of `lwork` returned by a workspace query generally provides better performance than the theoretical minimum value. The value of `lwork` returned by a workspace query is generally larger than the theoretical minimum value, but for very small matrices it can be smaller. The absolute minimum value of `lwork` is the minimum of the workspace query result and the theoretical minimum.

If you set `lwork` to a value less than the absolute minimum value and not equal to -1, the routine returns immediately with an error exit and does not provide information on the recommended workspace size.

?gejsv

Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method.

Syntax

```
call sgejsv(joba, jobu, jobv, jobr, jobt, jobp, m, n, a, lda, sva, u, ldu, v, ldv,
work, lwork, iwork, info)
```

```
call dgejsv(joba, jobu, jobv, jobr, jobt, jobp, m, n, a, lda, sva, u, ldu, v, ldv,
work, lwork, iwork, info)
```

Include Files

- `mkl.fi`

Description

The routine computes the singular value decomposition (SVD) of a real m -by- n matrix A , where $m \geq n$.

The SVD is written as

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix which is zero except for its n diagonal elements, U is an m -by- n (or m -by- m) orthonormal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array `sva`.

The `?gejsv` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The routine implements a preconditioned Jacobi SVD algorithm. It uses `?geqp3`, `?geqrf`, and `?gelqf` as preprocessors and preconditioners. Optionally, an additional row pivoting can be used as a preprocessor, which in some cases results in much higher accuracy. An example is matrix A with the structure $A = D1 * C * D2$, where $D1$, $D2$ are arbitrarily ill-conditioned diagonal matrices and C is a well-conditioned matrix. In that case, complete pivoting in the first QR factorizations provides accuracy dependent on the condition number of C , and independent of $D1$, $D2$. Such higher accuracy is not completely understood theoretically, but it works well in practice.

If A can be written as $A = B * D$, with well-conditioned B and some diagonal D , then the high accuracy is guaranteed, both theoretically and in software independent of D . For more details see [Drmac08-1], [Drmac08-2].

The computational range for the singular values can be the full range (`UNDERFLOW,OVERFLOW`), provided that the machine arithmetic and the BLAS and LAPACK routines called by `?gejsv` are implemented to work in that range. If that is not the case, the restriction for safe computation with the singular values in the range of normalized IEEE numbers is that the spectral condition number $\kappa(A) = \sigma_{\max}(A) / \sigma_{\min}(A)$ does not overflow. This code (`?gejsv`) is best used in this restricted range, meaning that singular values of magnitude below $\|A\|_2 / \text{slamch}('O')$ (for single precision) or $\|A\|_2 / \text{dlamch}('O')$ (for double precision) are returned as zeros. See `jobr` for details on this.

This implementation is slower than the one described in [Drmac08-1], [Drmac08-2] due to replacement of some non-LAPACK components, and because the choice of some tuning parameters in the iterative part (`?gesvj`) is left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: `?geqp3`) should be implemented as in [Drmac08-3].

If m is much larger than n , it is obvious that the initial QRF with column pivoting can be preprocessed by the QRF without pivoting. That well known trick is not used in `?gejsv` because in some cases heavy row weighting can be treated with complete pivoting. The overhead in cases m much larger than n is then only due to pivoting, but the benefits in accuracy have prevailed. You can incorporate this extra QRF step easily and also improve data movement (matrix transpose, matrix copy, matrix transposed copy) - this implementation of `?gejsv` uses only the simplest, naive data movement.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-

dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

joba

CHARACTER*1. Must be 'C', 'E', 'F', 'G', 'A', or 'R'.

Specifies the level of accuracy:

If *joba* = 'C', high relative accuracy is achieved if $A = B \cdot D$ with well-conditioned B and arbitrary diagonal matrix D . The accuracy cannot be spoiled by column scaling. The accuracy of the computed output depends on the condition of B , and the procedure aims at the best theoretical accuracy. The relative error $\max_{i=1:N} |\delta \sigma_i| / \sigma_i$ is bounded by $f(M,N) \cdot \epsilon \cdot \text{cond}(B)$, independent of D . The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of *joba*. Additional actions are specified as follows:

If *joba* = 'E', computation as with 'C' with an additional estimate of the condition number of B . It provides a realistic error bound.

If *joba* = 'F', accuracy higher than in the 'C' option is achieved, if $A = D1 \cdot C \cdot D2$ with ill-conditioned diagonal scalings $D1$, $D2$, and a well-conditioned matrix C . This option is advisable, if the structure of the input matrix is not known and relative accuracy is desirable. The input matrix A is preprocessed with QR factorization with full (row and column) pivoting.

If *joba* = 'G', computation as with 'F' with an additional estimate of the condition number of B , where $A = B \cdot D$. If A has heavily weighted rows, using this condition number gives too pessimistic error bound.

If *joba* = 'A', small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by $f(m,n) \cdot \epsilon \cdot \|A\|$. The computed SVD $A = U \cdot S \cdot V^T$ restores A up to $f(m,n) \cdot \epsilon \cdot \|A\|$. This enables the procedure to set all singular values below $n \cdot \epsilon \cdot \|A\|$ to zero.

If *joba* = 'R', the procedure is similar to the 'A' option. Rank revealing property of the initial QR factorization is used to reveal (using triangular factor) a gap $\sigma_{r+1} < \epsilon \cdot \sigma_r$, in which case the numerical rank is declared to be r . The SVD is computed with absolute error bounds, but more accurately than with 'A'.

jobu

CHARACTER*1. Must be 'U', 'F', 'W', or 'N'.

Specifies whether to compute the columns of the matrix U :

If *jobu* = 'U', n columns of U are returned in the array u

If *jobu* = 'F', a full set of m left singular vectors is returned in the array u .

If *jobu* = 'W', u may be used as workspace of length $m \cdot n$. See the description of u .

If *jobu* = 'N', *u* is not computed.

jobv

CHARACTER*1. Must be 'V', 'J', 'W', or 'N'.

Specifies whether to compute the matrix *V*:

If *jobv* = 'V', *n* columns of *V* are returned in the array *v*; Jacobi rotations are not explicitly accumulated.

If *jobv* = 'J', *n* columns of *V* are returned in the array *v* but they are computed as the product of Jacobi rotations. This option is allowed only if *jobu* ≠ 'N'.

If *jobv* = 'W', *v* may be used as workspace of length $n*n$. See the description of *v*.

If *jobv* = 'N', *v* is not computed.

jobr

CHARACTER*1. Must be 'N' or 'R'.

Specifies the range for the singular values. If small positive singular values are outside the specified range, they may be set to zero. If *A* is scaled so that the largest singular value of the scaled matrix is around $\sqrt{\text{big}}$, $\text{big} = \text{?lamch}('O')$, the function can remove columns of *A* whose norm in the scaled matrix is less than $\sqrt{\text{?lamch}('S')}$ (for *jobr* = 'R'), or less than $\text{small} = \text{?lamch}('S')/\text{?lamch}('E')$.

If *jobr* = 'N', the function does not remove small columns of the scaled matrix. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of *A* is greater than *big*, use *?gesvj*.

If *jobr* = 'R', restricted range for singular values of the scaled matrix *A* is $[\sqrt{\text{?lamch}('S')}, \sqrt{\text{big}}]$, roughly as described above. This option is recommended.

For computing the singular values in the full range $[\text{?lamch}('S'), \text{big}]$, use *?gesvj*.

jobt

CHARACTER*1. Must be 'T' or 'N'.

If the matrix is square, the procedure may determine to use a transposed *A* if A^T seems to be better with respect to convergence. If the matrix is not square, *jobt* is ignored. This is subject to changes in the future.

The decision is based on two values of entropy over the adjoint orbit of $A^T * A$. See the descriptions of *work(6)* and *work(7)*.

If *jobt* = 'T', the function performs transposition if the entropy test indicates possibly faster convergence of the Jacobi process, if *A* is taken as input. If *A* is replaced with A^T , the row pivoting is included automatically.

If *jobt* = 'N', the functions attempts no speculations. This option can be used to compute only the singular values, or the full SVD (*u*, *sigma*, and *v*). For only one set of singular vectors (*u* or *v*), the caller should provide both *u* and *v*, as one of the arrays is used as workspace if the matrix *A* is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of *u* and *v*.

jobp

CHARACTER*1. Must be 'P' or 'N'.

Enables structured perturbations of denormalized numbers. This option should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence. For details, see [Drmac08-1], [Drmac08-2]. For simplicity, such perturbations are included only when the full SVD or only the singular values are requested. You can add the perturbation for the cases of computing one set of singular vectors.

If $jobp = 'P'$, the function introduces perturbation.

If $jobp = 'N'$, the function introduces no perturbation.

m INTEGER. The number of rows of the input matrix A ; $m \geq 0$.

n INTEGER. The number of columns in the input matrix A ; $m \geq n \geq 0$.

$a, work, sva, u, v$ REAL for `sgejsv`

DOUBLE PRECISION for `dgejsv`.

Array $a(lda,*)$ is an array containing the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

sva is a workspace array, its size is n .

u is a workspace array, its size is $(ldu,*)$; the second dimension of u must be at least $\max(1, n)$.

v is a workspace array, its size is $(ldv,*)$; the second dimension of v must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array a . Must be at least $\max(1, m)$.

ldu INTEGER. The leading dimension of the array u ; $ldu \geq 1$.
 $jobu = 'U'$ or $'F'$ or $'W'$, $ldu \geq m$ for column major layout.

ldv INTEGER. The leading dimension of the array v ; $ldv \geq 1$.
 $jobv = 'V'$ or $'J'$ or $'W'$, $ldv \geq n$.

$lwork$ INTEGER.

Length of $work$ to confirm proper allocation of work space. $lwork$ depends on the task performed:

If only σ is needed ($jobu = 'N'$, $jobv = 'N'$) and

- ... no scaled condition estimate is required, then $lwork \geq \max(2*m+n, 4*n+1, 7)$. This is the minimal requirement. For optimal performance (blocked code) the optimal value is $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, 7)$. Here nb is the optimal block size for `?geqp3/?geqrf`.

In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(sgeqrf), 7)$ for `sgejsv`

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dgeqrf), 7)$ for `dgejsv`

- ... an estimate of the scaled condition number of A is required ($joba = 'E', 'G'$). In this case, $lwork$ is the maximum of the above and $n*n + 4*n$, that is, $lwork \geq \max(2*m+n, n*n+4*n, 7)$. For optimal performance (blocked code) the optimal value is $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, n*n+4*n, 7)$.

In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(sgeqrf), n+n*n + lwork(spocon, 7))$ for $sgejsv$

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dgeqrf), n+n*n + lwork(dpocon, 7))$ for $dgejsv$

If σ and the right singular vectors are needed ($jobv = 'V'$),

- the minimal requirement is $lwork \geq \max(2*m+n, 4*n+1, 7)$.
- for optimal performance, $lwork \geq \max(2*m+n, 3*n+(n+1)*nb, 7)$, where nb is the optimal block size for $?geqp3, ?geqrf, ?gelqf, ?ormlq$. In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(spocon), n + lwork(sgelqf), 2*n+lwork(sgeqrf), n+lwork(sormlq))$ for $sgejsv$

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dpocon), n + lwork(dgelqf), 2*n+lwork(dgeqrf), n+lwork(dormlq))$ for $dgejsv$

If σ and the left singular vectors are needed

- the minimal requirement is $lwork \geq \max(2*n+m, 4*n+1, 7)$.
- for optimal performance,
if $jobu = 'U' :: lwork \geq \max(2*m+n, 3*n+(n+1)*nb, 7)$,
if $jobu = 'F' :: lwork \geq \max(2*m+n, 3*n+(n+1)*nb, n+m*nb, 7)$,

where nb is the optimal block size for $?geqp3, ?geqrf, ?ormlq$. In general, the optimal length $lwork$ is computed as

$lwork \geq \max(2*m+n, n+lwork(sgeqp3), n+lwork(spocon), 2*n + lwork(sgeqrf), n+lwork(sormlq))$ for $sgejsv$

$lwork \geq \max(2*m+n, n+lwork(dgeqp3), n+lwork(dpocon), 2*n + lwork(dgeqrf), n+lwork(dormlq))$ for $dgejsv$

Here $lwork(?ormlq)$ equals $n*nb$ (for $jobu = 'U'$) or $m*nb$ (for $jobu = 'F'$)

If full SVD is needed ($jobu = 'U'$ or $'F'$) and

- if $jobv = 'V'$,
the minimal requirement is $lwork \geq \max(2*m+n, 6*n+2*n*n)$
- if $jobv = 'J'$,
the minimal requirement is $lwork \geq \max(2*m+n, 4*n+n*n, 2*n+n*n + 6)$
- For optimal performance, $lwork$ should be additionally larger than $n + m*nb$, where nb is the optimal block size for $?ormlq$.

iwork INTEGER. Workspace array, size $\max(3, m+3*n)$.

Output Parameters

sva

On exit:

For $work(1)/work(2) = one$: the singular values of A . During the computation *sva* contains Euclidean column norms of the iterated matrices in the array *a*.

For $work(1) \neq work(2)$: the singular values of A are $(work(1)/work(2)) * sva(1:n)$. This factored form is used if $\sigma_{max}(A)$ overflows or if small singular values have been saved from underflow by scaling the input matrix A .

$jobr = 'R'$, some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

u

On exit:

If $jobu = 'U'$, contains the m -by- n matrix of the left singular vectors.

If $jobu = 'F'$, contains the m -by- m matrix of the left singular vectors, including an orthonormal basis of the orthogonal complement of the range of A .

If $jobu = 'W'$ and $jobv = 'V'$, $jobt = 'T'$, and $m = n$, then *u* is used as workspace if the procedure replaces A with A^T . In that case, *v* is computed in *u* as left singular vectors of A^T and copied back to the *v* array. This 'W' option is just a reminder to the caller that in this case *u* is reserved as workspace of length $n*n$.

If $jobu = 'N'$, *u* is not referenced.

v

On exit:

If $jobv = 'V'$ or $'J'$, contains the n -by- n matrix of the right singular vectors.

If $jobv = 'W'$ and $jobu = 'U'$, $jobt = 'T'$, and $m = n$, then *v* is used as workspace if the procedure replaces A with A^T . In that case, *u* is computed in *v* as right singular vectors of A^T and copied back to the *u* array. This 'W' option is just a reminder to the caller that in this case *v* is reserved as workspace of length $n*n$.

If $jobv = 'N'$, *v* is not referenced.

work

On exit,

$work(1) = scale = work(2)/work(1)$ is the scaling factor such that $scale*sva(1:n)$ are the computed singular values of A . See the description of *sva()*.

$work(2) =$ see the description of $work(1)$.

$work(3) = sconda$ is an estimate for the condition number of column equilibrated A . If $joba = 'E'$ or $'G'$, $sconda$ is an estimate of $\sqrt{(|R|^{**t} * R)^{**(-1)} | | _1}$. It is computed using `?pocon`. It holds $n^{**(-1/4)} * sconda \leq | | R^{**(-1)} | | _2 \leq n^{**(1/4)} * sconda$, where R

is the triangular factor from the QRF of A . However, if R is truncated and the numerical rank is determined to be strictly smaller than n , *sconda* is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provided for a user who is familiar with the details of the method.

work(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization.

work(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if *jobt* = 'T'. They are provided for a user who is familiar with the details of the method.

work(6) = the entropy of $A^{**t}A$: : this is the Shannon entropy of $\text{diag}(A^{**t}A) / \text{Trace}(A^{**t}A)$ taken as point in the probability simplex.

work(7) = the entropy of A^*A^{**t} .

iwork

INTEGER. On exit,

iwork(1) = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of *joba* and *jobr*.

iwork(2) = the number of the computed nonzero singular value.

iwork(3) = if nonzero, a warning message. If *iwork*(3)=1, some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number of sweeps. The computed values may be inaccurate.

Description

The routine computes the singular value decomposition (SVD) of a real m -by- n matrix A , where $m \geq n$.

The SVD of A is written as

$$A = U \Sigma V^T,$$

where Σ is an m -by- n diagonal matrix, U is an m -by- n orthonormal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array `sva`.

The `?gesvj` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The n -by- n orthogonal matrix V is obtained as a product of Jacobi plane rotations. The rotations are implemented as fast scaled rotations of Anda and Park [[AndaPark94](#)]. In the case of underflow of the Jacobi angle, a modified Jacobi transformation of Drmac ([[Drmac08-4](#)]) is used. Pivot strategy uses column interchanges of de Rijk ([[deRijk98](#)]). The relative accuracy of the computed singular values and the accuracy of the computed singular vectors (in angle metric) is as guaranteed by the theory of Demmel and Veselic [[Demmel92](#)]. The condition number that determines the accuracy in the full rank case is essentially

$$(\min_i d_{ii}) \cdot \kappa(A \cdot D)$$

where $\kappa(\cdot)$ is the spectral condition number. The best performance of this Jacobi SVD procedure is achieved if used in an accelerated version of Drmac and Veselic [[Drmac08-1](#)], [[Drmac08-2](#)].

The computational range for the nonzero singular values is the machine number interval (`UNDERFLOW,OVERFLOW`). In extreme cases, even denormalized singular values can be computed with the corresponding gradual loss of accurate digit.

Input Parameters

<code>joba</code>	<p>CHARACTER*1. Must be 'L', 'U' or 'G'.</p> <p>Specifies the structure of A:</p> <p>If <code>joba</code> = 'L', the input matrix A is lower triangular.</p> <p>If <code>joba</code> = 'U', the input matrix A is upper triangular.</p> <p>If <code>joba</code> = 'G', the input matrix A is a general m-by-n, $m \geq n$.</p>
<code>jobu</code>	<p>CHARACTER*1. Must be 'U', 'C' or 'N'.</p> <p>Specifies whether to compute the left singular vectors (columns of U):</p> <p>If <code>jobu</code> = 'U', the left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of <code>a</code>. The default numerical orthogonality threshold is set to approximately $\text{TOL} = \text{CTOL} * \text{EPS}$, $\text{CTOL} = \sqrt{m}$, $\text{EPS} = \text{?lamch}('E')$</p> <p>If <code>jobu</code> = 'C', analogous to <code>jobu</code> = 'U', except that you can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to $\text{TOL} = \text{CTOL} * \text{EPS}$, where CTOL is given on input in the array</p>

work. No CTOL smaller than ONE is allowed. CTOL greater than 1 / EPS is meaningless. The option 'C' can be used if $m \cdot \text{EPS}$ is satisfactory orthogonality of the computed left singular vectors, so $\text{CTOL}=m$ could save a few sweeps of Jacobi rotations. See the descriptions of *a* and *work(1)*.

If *jobu* = 'N', *u* is not computed. However, see the description of *a*.

jobv

CHARACTER*1. Must be 'V', 'A' or 'N'.

Specifies whether to compute the right singular vectors, that is, the matrix *V*:

If *jobv* = 'V', the matrix *V* is computed and returned in the array *v*.

If *jobv* = 'A', the Jacobi rotations are applied to the *mv*-by-*n* array *v*. In other words, the right singular vector matrix *V* is not computed explicitly, instead it is applied to an *mv*-by-*n* matrix initially stored in the first *mv* rows of *V*.

If *jobv* = 'N', the matrix *V* is not computed and the array *v* is not referenced.

m

INTEGER. The number of rows of the input matrix *A*.

1/slamch('E') > $m \geq 0$ for sgesvj.

1/dlamch('E') > $m \geq 0$ for dgesvj.

n

INTEGER. The number of columns in the input matrix *A*; $m \geq n \geq 0$.

a, *work*, *sva*, *v*

REAL for sgesvj

DOUBLE PRECISION for dgesvj.

Array *a(lda,*)* is an array containing the *m*-by-*n* matrix *A*.

The second dimension of *a* is $\max(1, n)$.

work is a workspace array, its dimension $\max(4, m+n)$.

If *jobu* = 'C', *work(1)*=CTOL, where CTOL defines the threshold for convergence. The process stops if all columns of *A* are mutually orthogonal up to $\text{CTOL} \cdot \text{EPS}$, $\text{EPS} = \text{?lamch('E')}$. It is required that $\text{CTOL} \geq 1$, that is, it is not allowed to force the routine to obtain orthogonality below ϵ .

sva is a workspace array, its dimension is *n*.

Array *v* is a workspace array, its dimension is (*ldv*,*); the second dimension of *u* must be at least $\max(1, n)$.

lda

INTEGER. The leading dimension of the array *a*. Must be at least $\max(1, m)$.

mv

INTEGER.

If *jobv* = 'A', the product of Jacobi rotations in ?gesvj is applied to the first *mv* rows of *v*. See the description of *jobv*. $0 \leq mv \leq ldv$.

ldv

INTEGER. The leading dimension of the array *v*; $ldv \geq 1$.

jobv = 'V', $ldv \geq \max(1, n)$.

jobv = 'A', $ldv \geq \max(1, mv)$.

lwork

INTEGER.

Length of *work*, $work \geq \max(6, m+n)$.

Output Parameters

a

On exit:

If *jobu* = 'U' or *jobu* = 'C':

- if *info* = 0, the leading columns of *A* contain left singular vectors corresponding to the computed singular values of *a* that are above the underflow threshold $\text{?lamch}('S')$, that is, non-zero singular values. The number of the computed non-zero singular values is returned in *work*(2). Also see the descriptions of *sva* and *work*. The computed columns of *u* are mutually numerically orthogonal up to approximately $\text{TOL} = \sqrt{m} * \text{EPS}$ (default); or $\text{TOL} = \text{CTOL} * \text{EPS}$ *jobu* = 'C', see the description of *jobu*.
- if *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps). In that case, the computed columns of *u* may not be orthogonal up to *TOL*. The output *u* (stored in *a*), *sigma* (given by the computed singular values in *sva*(1:n)) and *v* is still a decomposition of the input matrix *A* in the sense that the residual $\|A - \text{scale} * U * \text{sigma} * V^T\|_2 / \|A\|_2$ (where *scale* = *stat*[0]) is small.

If *jobu* = 'N':

- if *info* = 0, note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of *u* is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately $m * \text{EPS}$. Thus, on exit, *a* contains the columns of *u* scaled with the corresponding singular values.
- if *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps).

sva

On exit:

If *info* = 0, depending on the value *scale* = *work*(1), where *scale* is the scaling factor:

- if *scale* = 1, *sva*(1:n) contains the computed singular values of *a*.
During the computation, *sva* contains the Euclidean column norms of the iterated matrices in the array *a*.
- if *scale* ≠ 1, the singular values of *a* are *scale***sva*(1:n), and this factored representation is due to the fact that some of the singular values of *a* might underflow or overflow.

If *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps) and *scale***sva*(1:n) may not be accurate.*v*

On exit:

If *jobv* = 'V', contains the *n*-by-*n* matrix of the right singular vectors.If *jobv* = 'A', then *v* contains the product of the computed right singular vector matrix and the initial matrix in the array *v*.

If `jobv = 'N'`, `v` is not referenced.

work

On exit,

`work(1) = scale` is the scaling factor such that `scale*sva(1:n)` are the computed singular values of `A`. See the description of `sva()`.

`work(2)` is the number of the computed nonzero singular value.

`work(3)` is the number of the computed singular values that are larger than the underflow threshold.

`work(4)` is the number of sweeps of Jacobi rotations needed for numerical convergence.

`work(5) = max_{i≠j} |COS(A(:,i),A(:,j))|` in the last sweep. This is useful information in cases when `?gesvj` did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

`work(6)` is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

info

INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

If `info > 0`, the function did not converge in the maximal number (30) of sweeps. The output may still be useful. See the description of *work*.

Description

The routine computes the generalized singular value decomposition (GSVD) of an m -by- n real/complex matrix A and p -by- n real/complex matrix B :

$$U'^* A Q = D_1 \begin{pmatrix} I & R \\ 0 & 0 \end{pmatrix}, \quad V'^* B Q = D_2 \begin{pmatrix} I & R \\ 0 & 0 \end{pmatrix},$$

where U , V and Q are orthogonal/unitary matrices and U' , V' mean transpose/conjugate transpose of U and V respectively.

Let $k+l$ = the effective numerical rank of the matrix (A', B') , then R is a $(k+l)$ -by- $(k+l)$ nonsingular upper triangular matrix, D_1 and D_2 are m -by- $(k+l)$ and p -by- $(k+l)$ "diagonal" matrices and of the following structures, respectively:

If $m-k-l \geq 0$,

$$D_1 = \begin{pmatrix} I_{k+l} & & \\ & 0 & \\ & & 0 \end{pmatrix}$$

$$D_2 = \begin{pmatrix} I_k & & \\ & S & \\ & & 0 \end{pmatrix}$$

$$D_1 = \begin{pmatrix} I_{k+l} & & \\ & 0 & \\ & & 0 \end{pmatrix} \quad D_2 = \begin{pmatrix} I_k & & \\ & S & \\ & & 0 \end{pmatrix}$$

where

$$C = \text{diag}(\alpha(K+1), \dots, \alpha(K+l))$$

$$S = \text{diag}(\beta(K+1), \dots, \beta(K+l))$$

$$C^2 + S^2 = I$$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$D_1 = \begin{pmatrix} I_{k+l} & & \\ & 0 & \\ & & 0 \end{pmatrix} \quad D_2 = \begin{pmatrix} I_k & & \\ & S & \\ & & 0 \end{pmatrix}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} 0 & S & 0 \end{pmatrix} \\ k+l-m & \begin{pmatrix} 0 & 0 & I \end{pmatrix} \\ p-l & \begin{pmatrix} 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \end{pmatrix} \\ m-k & \begin{pmatrix} 0 & 0 & R_{22} & R_{23} \end{pmatrix} \\ k+l-m & \begin{pmatrix} 0 & 0 & 0 & R_{33} \end{pmatrix} \end{matrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m)),$

$S = \text{diag}(\beta(K+1), \dots, \beta(m)),$

$C_2 + S_2 = I$

$\begin{pmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \end{pmatrix}$

On exit, $\begin{pmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The routine computes C, S, R , and optionally the orthogonal/unitary transformation matrices U, V and Q .

In particular, if B is an n -by- n nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A*B^{-1}$:

$$A*B^{-1} = U*(D_1*D_2^{-1})*V'.$$

If (A', B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A'*A*x = \lambda*B'*B*x.$$

Input Parameters

jobu CHARACTER*1. Must be 'U' or 'N'.
If **jobu** = 'U', orthogonal/unitary matrix U is computed.
If **jobu** = 'N', U is not computed.

jobv CHARACTER*1. Must be 'V' or 'N'.
If **jobv** = 'V', orthogonal/unitary matrix V is computed.
If **jobv** = 'N', V is not computed.

jobq CHARACTER*1. Must be 'Q' or 'N'.
If **jobq** = 'Q', orthogonal/unitary matrix Q is computed.
If **jobq** = 'N', Q is not computed.

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix <i>B</i> ($p \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	<p>REAL for sggsvd</p> <p>DOUBLE PRECISION for dggsvd</p> <p>COMPLEX for cggsvd</p> <p>DOUBLE COMPLEX for zggsvd.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the <i>p</i>-by-<i>n</i> matrix <i>B</i>.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p><i>work</i>(*) is a workspace array.</p> <p>The dimension of <i>work</i> must be at least $\max(3n, m, p) + n$.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; at least $\max(1, p)$.
<i>ldu</i>	<p>INTEGER. The leading dimension of the array <i>u</i> .</p> <p>$ldu \geq \max(1, m)$ if <i>jobu</i> = 'U'; $ldu \geq 1$ otherwise.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i> .</p> <p>$ldv \geq \max(1, p)$ if <i>jobv</i> = 'V'; $ldv \geq 1$ otherwise.</p>
<i>ldq</i>	<p>INTEGER. The leading dimension of the array <i>q</i> .</p> <p>$ldq \geq \max(1, n)$ if <i>jobq</i> = 'Q'; $ldq \geq 1$ otherwise.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, size at least $\max(1, n)$.</p>
<i>rwork</i>	<p>REAL for cggsvd DOUBLE PRECISION for zggsvd.</p> <p>Workspace array, size at least $\max(1, 2n)$. Used in complex flavors only.</p>

Output Parameters

<i>k</i> , <i>l</i>	INTEGER. On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks. The sum $k+l$ is equal to the effective numerical rank of (A', B') .
<i>a</i>	On exit, <i>a</i> contains the triangular matrix <i>R</i> or part of <i>R</i> .
<i>b</i>	On exit, <i>b</i> contains part of the triangular matrix <i>R</i> if $m-k-l < 0$.
<i>alpha</i> , <i>beta</i>	<p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors.</p>

Arrays, size at least $\max(1, n)$ each.

Contain the generalized singular value pairs of A and B :

$\alpha(1:k) = 1,$

$\beta(1:k) = 0,$

and if $m-k-l \geq 0,$

$\alpha(k+1:k+l) = C,$

$\beta(k+1:k+l) = S,$

or if $m-k-l < 0,$

$\alpha(k+1:m) = C, \alpha(m+1:k+l) = 0$

$\beta(k+1:m) = S, \beta(m+1:k+l) = 1$

and

$\alpha(k+l+1:n) = 0$

$\beta(k+l+1:n) = 0.$

u, v, q

REAL for sggsvd

DOUBLE PRECISION for dggsvd

COMPLEX for cggsvd

DOUBLE COMPLEX for zggsvd.

Arrays:

$u(ldu,*)$; the second dimension of u must be at least $\max(1, m)$.

If $jobu = 'U', u$ contains the m -by- m orthogonal/unitary matrix U .

If $jobu = 'N', u$ is not referenced.

$v(ldv,*)$; the second dimension of v must be at least $\max(1, p)$.

If $jobv = 'V', v$ contains the p -by- p orthogonal/unitary matrix V .

If $jobv = 'N', v$ is not referenced.

$q(ldq,*)$; the second dimension of q must be at least $\max(1, n)$.

If $jobq = 'Q', q$ contains the n -by- n orthogonal/unitary matrix Q .

If $jobq = 'N', q$ is not referenced.

$iwork$

On exit, $iwork$ stores the sorting information.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the Jacobi-type procedure failed to converge. For further details, see subroutine [tgsja](#).

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `ggsvd` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>b</code>	Holds the matrix B of size (p, n) .
<code>alpha</code>	Holds the vector of length n .
<code>beta</code>	Holds the vector of length n .
<code>u</code>	Holds the matrix U of size (m, m) .
<code>v</code>	Holds the matrix V of size (p, p) .
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>iwork</code>	Holds the vector of length n .
<code>jobu</code>	Restored based on the presence of the argument u as follows: <code>jobu</code> = 'U', if u is present, <code>jobu</code> = 'N', if u is omitted.
<code>jobv</code>	Restored based on the presence of the argument v as follows: <code>jobz</code> = 'V', if v is present, <code>jobz</code> = 'N', if v is omitted.
<code>jobq</code>	Restored based on the presence of the argument q as follows: <code>jobz</code> = 'Q', if q is present, <code>jobz</code> = 'N', if q is omitted.

Cosine-Sine Decomposition

This section describes LAPACK driver routines for computing the *cosine-sine decomposition* (CS decomposition). You can also call the corresponding computational routines to perform the same task.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Driver Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines (FORTRAN 77 interface) that perform CS decomposition of matrices. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of a block-partitioned orthogonal matrix	<code>orcsd uncsd</code> <code>orcsd2by1 uncsd2by1</code>	
Compute the CS decomposition of a block-partitioned unitary matrix		<code>orcsd uncsd</code>

Description

The routines ?orcsd/?uncsd compute the CS decomposition of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | \\ & u_2 \end{pmatrix} \left(\begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & C & 0 & 0 & -S & 0 \\ 0 & 0 & 0 & 0 & 0 & -I \\ \hline 0 & 0 & 0 & I & 0 & 0 \\ 0 & S & 0 & 0 & C & 0 \\ 0 & 0 & I & 0 & 0 & 0 \end{array} \right) \begin{pmatrix} v_1 & | \\ & v_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | \\ & u_2 \end{pmatrix} \left(\begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & C & 0 & 0 & -S & 0 \\ 0 & 0 & 0 & 0 & 0 & -I \\ \hline 0 & 0 & 0 & I & 0 & 0 \\ 0 & S & 0 & 0 & C & 0 \\ 0 & 0 & I & 0 & 0 & 0 \end{array} \right) \begin{pmatrix} v_1 & | \\ & v_2 \end{pmatrix}^H$$

x_{11} is p -by- q . The orthogonal/unitary matrices u_1 , u_2 , v_1 , and v_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

<i>jobu1</i>	CHARACTER. If equals <i>Y</i> , then u_1 is computed. Otherwise, u_1 is not computed.
<i>jobu2</i>	CHARACTER. If equals <i>Y</i> , then u_2 is computed. Otherwise, u_2 is not computed.
<i>jobv1t</i>	CHARACTER. If equals <i>Y</i> , then v_1^t is computed. Otherwise, v_1^t is not computed.
<i>jobv2t</i>	CHARACTER. If equals <i>Y</i> , then v_2^t is computed. Otherwise, v_2^t is not computed.
<i>trans</i>	CHARACTER = 'T': x , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order. otherwise x , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order.
<i>signs</i>	CHARACTER = 'O': The lower-left block is made nonpositive (the "other" convention). otherwise The upper-right block is made nonpositive (the "default" convention).
<i>m</i>	INTEGER. The number of rows and columns of the matrix X .
<i>p</i>	INTEGER. The number of rows in x_{11} and x_{12} . $0 \leq p \leq m$.
<i>q</i>	INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq m$.
<i>x11</i> , <i>x12</i> , <i>x21</i> , <i>x22</i>	REAL for sorcsd DOUBLE PRECISION for dorcsd COMPLEX for cuncsd DOUBLE COMPLEX for zuncsd Arrays of size <i>x11</i> ($ldx11, q$), <i>x12</i> ($ldx12, m - q$), <i>x21</i> ($ldx21, q$), and <i>x22</i> ($ldx22, m - q$). Contain the parts of the orthogonal/unitary matrix whose CSD is desired.
<i>ldx11</i> , <i>ldx12</i> , <i>ldx21</i> , <i>ldx22</i>	INTEGER. The leading dimensions of the parts of array X . $ldx11 \geq \max(1, p)$, $ldx12 \geq \max(1, p)$, $ldx21 \geq \max(1, m - p)$, $ldx22 \geq \max(1, m - p)$.
<i>ldu1</i>	INTEGER. The leading dimension of the array u_1 . If <i>jobu1</i> = 'Y', $ldu1 \geq \max(1, p)$.

<i>ldu2</i>	INTEGER. The leading dimension of the array u_2 . If $jobu2 = 'Y'$, $ldu2 \geq \max(1, m-p)$.
<i>ldv1t</i>	INTEGER. The leading dimension of the array $v1t$. If $jobv1t = 'Y'$, $ldv1t \geq \max(1, q)$.
<i>ldv2t</i>	INTEGER. The leading dimension of the array $v2t$. If $jobv2t = 'Y'$, $ldv2t \geq \max(1, m-q)$.
<i>work</i>	REAL for sorcsd DOUBLE PRECISION for dorcsd COMPLEX for cuncsd DOUBLE COMPLEX for zuncsd Workspace array, size $(\max(1, lwork))$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.
<i>rwork</i>	REAL for cuncsd DOUBLE PRECISION for zuncsd Workspace array, size $(\max(1, lrwork))$.
<i>lrwork</i>	INTEGER. The size of the <i>rwork</i> array. Constraints: If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>rwork</i> array, returns this value as the first entry of the <i>rwork</i> array, and no error message related to <i>lrwork</i> is issued by xerbla.
<i>iwork</i>	INTEGER. Workspace array, dimension m .

Output Parameters

<i>theta</i>	REAL for sorcsd DOUBLE PRECISION for dorcsd COMPLEX for cuncsd DOUBLE COMPLEX for zuncsd Array, size (r) , in which $r = \min(p, m-p, q, m-q)$. $C = \text{diag}(\cos(\theta(1)), \dots, \cos(\theta(r)))$, and $S = \text{diag}(\sin(\theta(1)), \dots, \sin(\theta(r)))$.
<i>u1</i>	REAL for sorcsd DOUBLE PRECISION for dorcsd COMPLEX for cuncsd

	DOUBLE COMPLEX for zuncsd
	Array, size (p).
	If $jobu1 = 'Y'$, $u1$ contains the p -by- p orthogonal/unitary matrix u_1 .
$u2$	REAL for sorcsd
	DOUBLE PRECISION for dorcsd
	COMPLEX for cuncsd
	DOUBLE COMPLEX for zuncsd
	Array, size ($ldu2, m-p$).
	If $jobu2 = 'Y'$, $u2$ contains the $(m-p)$ -by- $(m-p)$ orthogonal/unitary matrix u_2 .
$v1t$	REAL for sorcsd
	DOUBLE PRECISION for dorcsd
	COMPLEX for cuncsd
	DOUBLE COMPLEX for zuncsd
	Array, size ($ldv1t, *$) .
	If $jobv1t = 'Y'$, $v1t$ contains the q -by- q orthogonal matrix v_1^T or unitary matrix v_1^H .
$v2t$	REAL for sorcsd
	DOUBLE PRECISION for dorcsd
	COMPLEX for cuncsd
	DOUBLE COMPLEX for zuncsd
	Array, size ($ldv2t, m-q$).
	If $jobv2t = 'Y'$, $v2t$ contains the $(m-q)$ -by- $(m-q)$ orthogonal matrix v_2^T or unitary matrix v_2^H .
$work$	On exit,
	If $info = 0$, $work(1)$ returns the optimal $lwork$.
	If $info > 0$, For ?orcsd, $work(2:r)$ contains the values $phi(1), \dots, phi(r-1)$ that, together with $theta(1), \dots, theta(r)$ define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. $info$ specifies the number of nonzero phi 's.
$rwork$	On exit,
	If $info = 0$, $rwork(1)$ returns the optimal $lrwork$.
	If $info > 0$, For ?uncsd, $rwork(2:r)$ contains the values $phi(1), \dots, phi(r-1)$ that, together with $theta(1), \dots, theta(r)$ define the matrix in

intermediate bidiagonal-block form remaining after nonconvergence. *info* specifies the number of nonzero *phi*'s.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument has an illegal value
 > 0: ?orcsd/?uncsd did not converge. See the description of *work* above for details.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ?orcsd/?uncsd interface are as follows:

<i>x11</i>	Holds the block of matrix <i>X</i> of size (<i>p</i> , <i>q</i>).
<i>x12</i>	Holds the block of matrix <i>X</i> of size (<i>p</i> , <i>m-q</i>).
<i>x21</i>	Holds the block of matrix <i>X</i> of size (<i>m-p</i> , <i>q</i>).
<i>x22</i>	Holds the block of matrix <i>X</i> of size (<i>m-p</i> , <i>m-q</i>).
<i>theta</i>	Holds the vector of length $r = \min(p, m-p, q, m-q)$.
<i>u1</i>	Holds the matrix of size (<i>p</i> , <i>p</i>).
<i>u2</i>	Holds the matrix of size (<i>m-p</i> , <i>m-p</i>).
<i>v1t</i>	Holds the matrix of size (<i>q</i> , <i>q</i>).
<i>v2t</i>	Holds the matrix of size (<i>m-q</i> , <i>m-q</i>).
<i>jobsu1</i>	Indicates whether <i>u</i> ₁ is computed. Must be 'Y' or 'O'.
<i>jobsu2</i>	Indicates whether <i>u</i> ₂ is computed. Must be 'Y' or 'O'.
<i>jobv1t</i>	Indicates whether <i>v</i> ₁ ^{<i>t</i>} is computed. Must be 'Y' or 'O'.
<i>jobv2t</i>	Indicates whether <i>v</i> ₂ ^{<i>t</i>} is computed. Must be 'Y' or 'O'.
<i>trans</i>	Must be 'N' or 'T'.
<i>signs</i>	Must be 'O' or 'D'.

Description

The routines ?orcsd2by1/?uncscsd2by1 compute the CS decomposition of an m -by- q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

$$X = \begin{bmatrix} X_{11} \\ X_{21} \end{bmatrix} = \begin{bmatrix} U_1 & | \\ \hline & U_2 \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & C & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & S & 0 \\ 0 & 0 & I \end{bmatrix} V_1^H$$

X_{11} is p -by- q . The orthogonal/unitary matrices u_1 , u_2 , v_1 , and v_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

<i>jobu1</i>	CHARACTER. If equal to 'Y', then u_1 is computed. Otherwise, u_1 is not computed.
<i>jobu2</i>	CHARACTER. If equal to 'Y', then u_2 is computed. Otherwise, u_2 is not computed.
<i>jobv1t</i>	CHARACTER. If equal to 'Y', then v_1^t is computed. Otherwise, v_1^t is not computed.
<i>m</i>	INTEGER. The number of rows and columns of the matrix X .
<i>p</i>	INTEGER. The number of rows in x_{11} . $0 \leq p \leq m$.
<i>q</i>	INTEGER. The number of columns in x_{11} . $0 \leq q \leq m$.
<i>x11</i>	REAL for sorcsd2by1

	DOUBLE PRECISION for dorcsd2by1 COMPLEX for cuncsd2by1 DOUBLE COMPLEX for zuncsd2by1 Array, size ($ldx11, q$). On entry, the part of the orthogonal matrix whose CSD is desired.
<i>ldx11</i>	INTEGER. The leading dimension of the array <i>x11</i> . $ldx11 \geq \max(1, p)$.
<i>x21</i>	REAL for sorcsd2by1 DOUBLE PRECISION for dorcsd2by1 COMPLEX for cuncsd2by1 DOUBLE COMPLEX for zuncsd2by1 Array, size ($ldx21, q$). On entry, the part of the orthogonal matrix whose CSD is desired.
<i>ldx21</i>	INTEGER. The leading dimension of the array <i>X</i> . $ldx21 \geq \max(1, m - p)$.
<i>ldu1</i>	INTEGER. The leading dimension of the array u_1 . If <i>jobu1</i> = 'Y', $ldu1 \geq \max(1, p)$.
<i>ldu2</i>	INTEGER. The leading dimension of the array u_2 . If <i>jobu2</i> = 'Y', $ldu2 \geq \max(1, m-p)$.
<i>ldv1t</i>	INTEGER. The leading dimension of the array $v1t$. If <i>jobv1t</i> = 'Y', $ldv1t \geq \max(1, q)$.
<i>work</i>	REAL for sorcsd2by1 DOUBLE PRECISION for dorcsd2by1 COMPLEX for cuncsd2by1 DOUBLE COMPLEX for zuncsd2by1 Workspace array, size ($\max(1, lwork)$).
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.
<i>rwork</i>	REAL for cuncsd2by1 DOUBLE PRECISION for zuncsd2by1 Workspace array, size ($\max(1, lrwork)$).
<i>lrwork</i>	INTEGER. The size of the <i>rwork</i> array. Constraints:

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $rwork$ array, returns this value as the first entry of the $rwork$ array, and no error message related to $lrwork$ is issued by xerbla.

iwork INTEGER. Workspace array, dimension $m - \min(p, m - p, q, m - q)$.

Output Parameters

theta REAL for sorcsd2by1
 DOUBLE PRECISION for dorcsd2by1
 COMPLEX for cuncsd2by1
 DOUBLE COMPLEX for zuncsd2by1
 Array, size (r), in which $r = \min(p, m-p, q, m-q)$.
 $C = \text{diag}(\cos(\theta(1)), \dots, \cos(\theta(r)))$, and
 $S = \text{diag}(\sin(\theta(1)), \dots, \sin(\theta(r)))$.

u1 REAL for sorcsd2by1
 DOUBLE PRECISION for dorcsd2by1
 COMPLEX for cuncsd2by1
 DOUBLE COMPLEX for zuncsd2by1
 Array, size ($ldu1, p$).
 If $jobu1 = 'Y'$, $u1$ contains the p -by- p orthogonal/unitary matrix u_1 .

u2 REAL for sorcsd2by1
 DOUBLE PRECISION for dorcsd2by1
 COMPLEX for cuncsd2by1
 DOUBLE COMPLEX for zuncsd2by1
 Array, size ($ldu2, m-p$).
 If $jobu2 = 'Y'$, $u2$ contains the $(m-p)$ -by- $(m-p)$ orthogonal/unitary matrix u_2 .

v1t REAL for sorcsd2by1
 DOUBLE PRECISION for dorcsd2by1
 COMPLEX for cuncsd2by1
 DOUBLE COMPLEX for zuncsd2by1
 Array, size ($ldv1t, q$).
 If $jobv1t = 'Y'$, $v1t$ contains the q -by- q orthogonal matrix v_1^T or unitary matrix v_1^H .

work On exit,
 If $info = 0$, $work(1)$ returns the optimal $lwork$.

If $info > 0$, $work(2:r)$ contains the values $\phi(1), \dots, \phi(r-1)$ that, together with $\theta(1), \dots, \theta(r)$ define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. $info$ specifies the number of nonzero ϕ 's.

$rwork$

On exit,

If $info = 0$, $rwork(1)$ returns the optimal $lrwork$.

If $info > 0$, $rwork(2:r)$ contains the values $\phi(1), \dots, \phi(r-1)$ that, together with $\theta(1), \dots, \theta(r)$ define the matrix in intermediate bidiagonal-block form remaining after nonconvergence. $info$ specifies the number of nonzero ϕ 's.

$info$

INTEGER.

= 0: successful exit

< 0: if $info = -i$, the i -th argument has an illegal value

> 0: ?orcsd2by1/?uncsd2by1 did not converge. See the description of $work$ above for details.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ?orcsd2by1/?uncsd2by1 interface are as follows:

$x11$	Holds the block of matrix X_{11} of size (p, q) .
$x21$	Holds the block of matrix X_{21} of size $(m-p, q)$.
θ	Holds the vector of length $r = \min(p, m-p, q, m-q)$.
$u1$	Holds the matrix u_1 of size (p, p) .
$u2$	Holds the matrix u_2 of size $(m-p, m-p)$.
$v1t$	Holds the matrix v_1^T or v_1^H of size (q, q) .
$jobu1$	Indicates whether u_1 is computed. Must be 'Y' or 'O'.
$jobu2$	Indicates whether u_2 is computed. Must be 'Y' or 'O'.
$jobv1t$	Indicates whether v_1^t is computed. Must be 'Y' or 'O'.

Generalized Symmetric Definite Eigenproblems

This section describes LAPACK driver routines used for solving generalized symmetric definite eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Symmetric Definite Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized Symmetric Definite Eigenproblems

Routine Name	Operation performed
sygv/hegv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
sygvd/hegvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.
sygvx/hegvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
spgv/hpgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
spgvd/hpgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.
spgvx/hpgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
sbgv/hbgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.
sbgvd/hbgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.
sbgvx/hbgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.

?sygv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```
call ssygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
call dsygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
call sygv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Include Files

- `mk1.fi, lapack.f90`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3.</p> <p>Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>a, b, work</i>	<p>REAL for ssygv</p> <p>DOUBLE PRECISION for dsygv.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the upper or lower triangle of the symmetric positive definite matrix B, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of <i>a</i>; at least $\max(1, n)$.</p>
<i>ldb</i>	<p>INTEGER. The leading dimension of <i>b</i>; at least $\max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>;</p> <p>$lwork \geq \max(1, 3n-1)$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.</p> <p>See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	<p>On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>a</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows:</p> <p>if <i>itype</i> = 1 or 2, $Z^T * B * Z = I$;</p> <p>if <i>itype</i> = 3, $Z^T * \text{inv}(B) * Z = I$;</p> <p>If <i>jobz</i> = 'N', then on exit the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of <i>A</i>, including the diagonal, is destroyed.</p>
<i>b</i>	<p>On exit, if <i>info</i> ≤ <i>n</i>, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.</p>
<i>w</i>	<p>REAL for <i>ssygv</i></p> <p>DOUBLE PRECISION for <i>dsygv</i>.</p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues in ascending order.</p>
<i>work</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>work</i>(1) returns the required minimal size of <i>lwork</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.</p> <p>If <i>info</i> > 0, <i>spotrf</i>/<i>dpotrf</i> or <i>ssyev</i>/<i>dsyev</i> returned an error code:</p> <p>If <i>info</i> = <i>i</i> ≤ <i>n</i>, <i>ssyev</i>/<i>dsyev</i> failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero;</p> <p>If <i>info</i> = <i>n</i> + <i>i</i>, for $1 \leq i \leq n$, then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *sygv* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use $lwork \geq (nb+2)*n$, where nb is the blocksize for `ssytrd/dsytrd` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $work$ ($liwork$) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

```
call chegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
call zhegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
call hegv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if $itype = 1$, the problem type is $A^*x = \lambda^*B^*x$;</p> <p>if $itype = 2$, the problem type is $A^*B^*x = \lambda^*x$;</p> <p>if $itype = 3$, the problem type is $B^*A^*x = \lambda^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If $jobz = 'N'$, then compute eigenvalues only.</p> <p>If $jobz = 'V'$, then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If $uplo = 'U'$, arrays a and b store the upper triangles of A and B;</p>

If $uplo = 'L'$, arrays a and b store the lower triangles of A and B .

n INTEGER. The order of the matrices A and B ($n \geq 0$).

$a, b, work$ COMPLEX for `chegv`

DOUBLE COMPLEX for `zhegv`.

Arrays:

$a(lda,*)$ contains the upper or lower triangle of the Hermitian matrix A , as specified by $uplo$.

The second dimension of a must be at least $\max(1, n)$.

$b(l db,*)$ contains the upper or lower triangle of the Hermitian positive definite matrix B , as specified by $uplo$.

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$; $lwork \geq \max(1, 2n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$rwork$ REAL for `chegv`

DOUBLE PRECISION for `zhegv`.

Workspace array, size at least $\max(1, 3n-2)$.

Output Parameters

a On exit, if $jobz = 'V'$, then if $info = 0$, a contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^H * B * Z = I$;

if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is destroyed.

b On exit, if $info \leq n$, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.

w REAL for `chegv`

DOUBLE PRECISION for `zhegv`.

Array, size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

work(1) On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th argument has an illegal value.

If *info* > 0, *cpotrf/zpotrf* or *cheev/zheev* return an error code:

If *info* = *i* ≤ *n*, *cheev/zheev* fails to converge, and *i* off-diagonal elements of an intermediate tridiagonal do not converge to zero;

If *info* = *n* + *i*, for 1 ≤ *i* ≤ *n*, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* can not be completed and no eigenvalues or eigenvectors are computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *hegv* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use *lwork* ≥ (*nb*+1)**n*, where *nb* is the blocksize for *chetrd/zhetrd* returned by *ilaenv*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Syntax

```
call ssygvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, iwork, liwork, info)
call dsygvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, iwork, liwork, info)
call sygvd(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

It uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>a, b, work</i>	<p>REAL for ssygvd</p> <p>DOUBLE PRECISION for dsygvd.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the upper or lower triangle of the symmetric positive definite matrix B, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, n)$.</p>

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of *b*; at least $\max(1, n)$.

lwork INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lwork < 2n+1$;

If $jobz = 'V'$ and $n > 1$, $lwork < 2n^2+6n+1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.

Workspace array, its dimension $\max(1, lwork)$.

liwork INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

a On exit, if $jobz = 'V'$, then if $info = 0$, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T * B * Z = I$;

if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of *A*, including the diagonal, is destroyed.

b On exit, if $info \leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

w REAL for ssygvd

DOUBLE PRECISION for dsygvd.

Array, size at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$work(1)$ On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$iwork(1)$ On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, an error code is returned as specified below.

- For $info \leq n$:
 - If $info = i$ and $jobz = 'N'$, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
 - If $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$.
- For $info > n$:
 - If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sygvd` interface are the following:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size (n, n) .
w	Holds the vector of length n .
$itype$	Must be 1, 2, or 3. The default value is 1.
$jobz$	Must be 'N' or 'V'. The default value is 'N'.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem using a divide and conquer method.

Syntax

```
call chegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, lrwork,
iwork, liwork, info)

call zhegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, lrwork,
iwork, liwork, info)

call hegvd(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be Hermitian and *B* is also positive definite.

It uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda B^*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda B^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>

n	INTEGER. The order of the matrices A and B ($n \geq 0$).
$a, b, work$	COMPLEX for <code>chegvd</code> DOUBLE COMPLEX for <code>zhegvd</code> . Arrays: $a(lda,*)$ contains the upper or lower triangle of the Hermitian matrix A , as specified by <i>uplo</i> . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the upper or lower triangle of the Hermitian positive definite matrix B , as specified by <i>uplo</i> . The second dimension of b must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
$l db$	INTEGER. The leading dimension of b ; at least $\max(1, n)$.
$lwork$	INTEGER. The dimension of the array $work$. Constraints: If $n \leq 1, lwork \geq 1$; If $jobz = 'N'$ and $n > 1, lwork \geq n+1$; If $jobz = 'V'$ and $n > 1, lwork \geq n^2+2n$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work, rwork$ and $iwork$ arrays, returns these values as the first entries of the $work, rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by xerbla . See <i>Application Notes</i> for details.
$rwork$	REAL for <code>chegvd</code> DOUBLE PRECISION for <code>zhegvd</code> . Workspace array, size $\max(1, lrwork)$.
$lrwork$	INTEGER. The dimension of the array $rwork$. Constraints: If $n \leq 1, lrwork \geq 1$; If $jobz = 'N'$ and $n > 1, lrwork \geq n$; If $jobz = 'V'$ and $n > 1, lrwork \geq 2n^2+5n+1$. If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work, rwork$ and $iwork$ arrays, returns these values as the first entries of the $work, rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by xerbla . See <i>Application Notes</i> for details.

<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, size $\max(1, liwork)$.</p>
<i>liwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>iwork</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $liwork \geq 1$;</p> <p>If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;</p> <p>If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.</p> <p>If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>

Output Parameters

<i>a</i>	<p>On exit, if $jobz = 'V'$, then if $info = 0$, <i>a</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows:</p> <p>if $itype = 1$ or 2, $Z^H * B * Z = I$;</p> <p>if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;</p> <p>If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of <i>A</i>, including the diagonal, is destroyed.</p>
<i>b</i>	<p>On exit, if $info \leq n$, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.</p>
<i>w</i>	<p>REAL for <code>chegvd</code></p> <p>DOUBLE PRECISION for <code>zhegvd</code>.</p> <p>Array, size at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p>
<i>work</i> (1)	<p>On exit, if $info = 0$, then <i>work</i>(1) returns the required minimal size of <i>lwork</i>.</p>
<i>rwork</i> (1)	<p>On exit, if $info = 0$, then <i>rwork</i>(1) returns the required minimal size of <i>lrwork</i>.</p>
<i>iwork</i> (1)	<p>On exit, if $info = 0$, then <i>iwork</i>(1) returns the required minimal size of <i>liwork</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the <i>i</i>-th argument had an illegal value.</p>

If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $mod(info, n+1)$.

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hegv` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, n) .
<i>w</i>	Holds the vector of length n .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value ($work(1)$, $iwork(1)$, $rwork(1)$) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```
call ssygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, iwork, ifail, info)
```

```
call dsygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu, abstol, m,
w, z, ldz, work, lwork, iwork, ifail, info)
```

```
call sygvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>a</i> , <i>b</i> , <i>work</i>	<p>REAL for ssygvx</p> <p>DOUBLE PRECISION for dsygvx.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>

$b(ldb,*)$ contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by $uplo$.

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The leading dimension of b ; at least $\max(1, n)$.

vl, vu REAL for `ssygvx`
DOUBLE PRECISION for `dsygvx`.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$
if $n = 0$.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

$abstol$ REAL for `ssygvx`
DOUBLE PRECISION for `dsygvx`. The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array z . Constraints:
 $ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

$lwork$ INTEGER.
The dimension of the array $work$;
 $lwork < \max(1, 8n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$iwork$ INTEGER.

Workspace array, size at least $\max(1, 5n)$.

Output Parameters

a On exit, the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is overwritten.

<i>b</i>	On exit, if <i>info</i> ≤ <i>n</i> , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i> , and if <i>range</i> = 'I', <i>m</i> = <i>iu-il</i> +1.
<i>w, z</i>	REAL for ssygvx DOUBLE PRECISION for dsygvx. Arrays: <i>w</i> (*), size at least max(1, <i>n</i>). The first <i>m</i> elements of <i>w</i> contain the selected eigenvalues in ascending order. <i>z</i> (<i>ldz</i> ,*) . The second dimension of <i>z</i> must be at least max(1, <i>m</i>). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T * B * Z = I$; if <i>itype</i> = 3, $Z^T * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least max(1, <i>m</i>) columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>ifail</i>	INTEGER. Array, size at least max(1, <i>n</i>). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> th argument had an illegal value. If <i>info</i> > 0, spotrf/dpotrf and ssyevx/dsyevx returned an error code:

If $info = i \leq n$, `ssyevx/dsyevx` failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array `ifail`;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sygvx` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>z</code>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<code>ifail</code>	Holds the vector of length n .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>vl</code>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<code>vu</code>	Default value for this element is $vu = \text{HUGE}(vu)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0_WP$.
<code>jobz</code>	<p>Restored based on the presence of the argument <code>z</code> as follows:</p> <p>$jobz = 'V'$, if <code>z</code> is present,</p> <p>$jobz = 'N'$, if <code>z</code> is omitted.</p> <p>Note that there will be an error condition if <code>ifail</code> is present and <code>z</code> is omitted.</p>
<code>range</code>	<p>Restored based on the presence of arguments <code>vl</code>, <code>vu</code>, <code>il</code>, <code>iu</code> as follows:</p> <p>$range = 'V'$, if one of or both <code>vl</code> and <code>vu</code> are present,</p> <p>$range = 'I'$, if one of or both <code>il</code> and <code>iu</code> are present,</p> <p>$range = 'A'$, if none of <code>vl</code>, <code>vu</code>, <code>il</code>, <code>iu</code> is present,</p> <p>Note that there will be an error condition if one of or both <code>vl</code> and <code>vu</code> are present and at the same time one of or both <code>il</code> and <code>iu</code> are present.</p>

	<p>if $itype = 1$, the problem type is $A*x = \lambda*B*x$;</p> <p>if $itype = 2$, the problem type is $A*B*x = \lambda*x$;</p> <p>if $itype = 3$, the problem type is $B*A*x = \lambda*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If $jobz = 'N'$, then compute eigenvalues only.</p> <p>If $jobz = 'V'$, then compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If $range = 'A'$, the routine computes all eigenvalues.</p> <p>If $range = 'V'$, the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If $range = 'I'$, the routine computes eigenvalues with indices il to iu.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If $uplo = 'U'$, arrays a and b store the upper triangles of A and B;</p> <p>If $uplo = 'L'$, arrays a and b store the lower triangles of A and B.</p>
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b, work</i>	<p>COMPLEX for chegvx</p> <p>DOUBLE COMPLEX for zhegvx.</p> <p>Arrays:</p> <p>$a(lda,*)$ contains the upper or lower triangle of the Hermitian matrix A, as specified by $uplo$.</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>$b(l db,*)$ contains the upper or lower triangle of the Hermitian positive definite matrix B, as specified by $uplo$.</p> <p>The second dimension of b must be at least $\max(1, n)$.</p> <p>$work$ is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of b ; at least $\max(1, n)$.
<i>vl, vu</i>	<p>REAL for chegvx</p> <p>DOUBLE PRECISION for zhegvx.</p> <p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
<i>il, iu</i>	INTEGER.

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

REAL for chegvx

DOUBLE PRECISION for zhegvx.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array z. Constraints:

$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*; $lwork \geq \max(1, 2n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

rwork

REAL for chegvx

DOUBLE PRECISION for zhegvx.

Workspace array, size at least $\max(1, 7n)$.

iwork

INTEGER.

Workspace array, size at least $\max(1, 5n)$.

Output Parameters

a

On exit, the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of *A*, including the diagonal, is overwritten.

b

On exit, if $info \leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$,
 $m = iu - il + 1$.

w

REAL for chegvx

DOUBLE PRECISION for zhegvx.

Array, size at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues in ascending order.

z

COMPLEX for chegvx

DOUBLE COMPLEX for zhegvx.

Array $z(ldz,*)$. The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^H * B * Z = I$;

if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of *lwork*.

ifail

INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i th argument had an illegal value.

If $info > 0$, cpotrf/zpotrf and cheevx/zheevx returned an error code:

If $info = i \leq n$, cheevx/zheevx failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hegvx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length <i>n</i> .

<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p>$jobz = 'V'$, if <i>z</i> is present,</p> <p>$jobz = 'N'$, if <i>z</i> is omitted.</p> <p>Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows:</p> <p>$range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present,</p> <p>$range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present,</p> <p>$range = 'A'$, if none of <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> is present,</p> <p>Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.</p>

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *C* to tridiagonal form, where *C* is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{lamch}('S')$.

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the blocksize for `chetrd/zhetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

```
call sspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
call dspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
call spgv(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be symmetric, stored in packed format, and *B* is also positive definite.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda B^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda B^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap</i> , <i>bp</i> , <i>work</i>	REAL for sspgv DOUBLE PRECISION for dspgv.

Arrays:

ap(*) contains the packed upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.

The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.

bp(*) contains the packed upper or lower triangle of the symmetric matrix *B*, as specified by *uplo*.

The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.

work(*) is a workspace array, size at least $\max(1, 3n)$.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

Output Parameters

ap On exit, the contents of *ap* are overwritten.

bp On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as *B*.

w, z REAL for *sspgv*
DOUBLE PRECISION for *dspgv*.

Arrays:

w(*), size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

z(*ldz*,*) .

The second dimension of *z* must be at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^T * B * Z = I$;

if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;

If *jobz* = 'N', then *z* is not referenced.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th argument had an illegal value.

If *info* > 0, *spstrf*/*dpstrf* and *sspev*/*dspev* returned an error code:

If *info* = *i* ≤ *n*, *sspev*/*dspev* failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If *info* = *n* + *i*, for 1 ≤ *i* ≤ *n*, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `spgv` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: $jobz = 'V'$, if <code>z</code> is present, $jobz = 'N'$, if <code>z</code> is omitted.

?hpgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

```
call chpgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
call zhpv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
call hpgv(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

?spgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage using a divide and conquer method.

Syntax

```
call sspgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, iwork, liwork, info)
call dspgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, iwork, liwork, info)
call spgvd(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>ap</i> , <i>bp</i> , <i>work</i>	<p>REAL for <code>sspgvd</code></p> <p>DOUBLE PRECISION for <code>dspgvd</code>.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>bp</i>(*) contains the packed upper or lower triangle of the symmetric matrix B, as specified by <i>uplo</i>.</p> <p>The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraints:</p> <p>If $n \leq 1$, $lwork \geq 1$;</p>

If $jobz = 'N'$ and $n > 1$, $lwork \geq 2n$;

If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2 + 6n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, dimension $\max(1, lwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ap

On exit, the contents of *ap* are overwritten.

bp

On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as *B*.

w, *z*

REAL for *sspgv*

DOUBLE PRECISION for *dspgv*.

Arrays:

w(*), size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

z(*ldz*, *).

The second dimension of *z* must be at least $\max(1, n)$.

If $jobz = 'V'$, then if *info* = 0, *z* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^T * B * Z = I$;

if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then *z* is not referenced.

work(1)

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, <i>sppstrf</i> / <i>dpptstrf</i> and <i>sspevd</i> / <i>dspevd</i> returned an error code: If <i>info</i> = <i>i</i> ≤ <i>n</i> , <i>sspevd</i> / <i>dspevd</i> failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; If <i>info</i> = <i>n</i> + <i>i</i> , for 1 ≤ <i>i</i> ≤ <i>n</i> , then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *spgv*d interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>bp</i>	Holds the array <i>B</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hpgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage using a divide and conquer method.

Syntax

```
call chpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork, lrwork,
            iwork, liwork, info)

call zhpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork, lrwork,
            iwork, liwork, info)

call hpgvd(ap, bp, w [,itype] [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>ap</i> , <i>bp</i> , <i>work</i>	<p>COMPLEX for chpgvd</p> <p>DOUBLE COMPLEX for zhpgvd.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix A, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p>

bp(*) contains the packed upper or lower triangle of the Hermitian matrix *B*, as specified by *uplo*.

The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.

work is a workspace array, its dimension $\max(1, lwork)$.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

lwork INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If *jobz* = 'N' and $n > 1$, $lwork \geq n$;

If *jobz* = 'V' and $n > 1$, $lwork \geq 2n$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for chpgvd

DOUBLE PRECISION for zhpgvd.

Workspace array, its dimension $\max(1, lrwork)$.

lrwork INTEGER.

The dimension of the array *rwork*.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;

If *jobz* = 'N' and $n > 1$, $lrwork \geq n$;

If *jobz* = 'V' and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.

If *lrwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If *jobz* = 'N' and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as <i>B</i> .
<i>w</i>	REAL for <code>chpgvd</code> DOUBLE PRECISION for <code>zhpgvd</code> . Array, size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for <code>chpgvd</code> DOUBLE COMPLEX for <code>zhpgvd</code> . Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^H * B * Z = I$; if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$; If $jobz = 'N'$, then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, if $info = 0$, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if $info = 0$, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if $info = 0$, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th argument had an illegal value. If $info > 0$, <code>cpptrf/zpptrf</code> and <code>chpevd/zhpevd</code> returned an error code: If $info = i \leq n$, <code>chpevd/zhpevd</code> failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hpgvd` interface are the following:

<code>ap</code>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array <i>B</i> of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements <i>n</i> .
<code>z</code>	Holds the matrix <i>Z</i> of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument <i>z</i> as follows: <code>jobz = 'V'</code> , if <i>z</i> is present, <code>jobz = 'N'</code> , if <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

```
call sspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, iwork, ifail, info)

call dspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, iwork, ifail, info)

call spgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>ap, bp, work</i>	<p>REAL for <code>sspgvx</code></p> <p>DOUBLE PRECISION for <code>dspgvx</code>.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>.</p> <p>The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>bp</i>(*) contains the packed upper or lower triangle of the symmetric matrix B, as specified by <i>uplo</i>.</p> <p>The size of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$.</p>

work(*) is a workspace array, size at least $\max(1, 8n)$.

vl, *vu*

REAL for sspgvx

DOUBLE PRECISION for dspgvx.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu*

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for sspgvx

DOUBLE PRECISION for dspgvx.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array *z*. Constraints:

$ldz \geq 1$; if *jobz* = 'V', $ldz \geq \max(1, n)$.

iwork

INTEGER.

Workspace array, size at least $\max(1, 5n)$.

Output Parameters

ap

On exit, the contents of *ap* are overwritten.

bp

On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as *B*.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',

$m = iu - il + 1$.

w, *z*

REAL for sspgvx

DOUBLE PRECISION for dspgvx.

Arrays:

w(*), size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

z(*ldz*,*) .

The second dimension of *z* must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T B Z = I$;

if $itype = 3$, $Z^T \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, `sppttrf/dppttrf` and `sspevx/dspevx` returned an error code:

If $info = i \leq n$, `sspevx/dspevx` failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `spgvx` interface are the following:

<i>ap</i>	Holds the array A of size $(n*(n+1)/2)$.
<i>bp</i>	Holds the array B of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector with the number of elements n .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.

<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	<p>Restored based on the presence of the argument <i>z</i> as follows:</p> <p>$jobz = 'V'$, if <i>z</i> is present,</p> <p>$jobz = 'N'$, if <i>z</i> is omitted.</p> <p>Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.</p>
<i>range</i>	<p>Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows:</p> <p>$range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present,</p> <p>$range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present,</p> <p>$range = 'A'$, if none of <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> is present,</p> <p>Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.</p>

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot \|T\|_1$ is used instead, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 \cdot \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 \cdot \text{lamch}('S')$.

?hpgvx

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

```
call chpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, rwork, iwork, ifail, info)

call zhpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m, w, z,
ldz, work, rwork, iwork, ifail, info)

call hpgvx(ap, bp, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.</p>
<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of A and B.</p>
<i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>ap, bp, work</i>	<p>COMPLEX for <code>chpgvx</code></p> <p>DOUBLE COMPLEX for <code>zhpgvx</code>.</p> <p>Arrays:</p> <p><i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix A, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.</p> <p><i>bp</i>(*) contains the packed upper or lower triangle of the Hermitian matrix B, as specified by <i>uplo</i>.</p> <p>The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$.</p>

work(*) is a workspace array, size at least $\max(1, 2n)$.

vl, *vu*

REAL for *chpgvx*

DOUBLE PRECISION for *zhpgvx*.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu*

INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

REAL for *chpgvx*

DOUBLE PRECISION for *zhpgvx*.

The absolute error tolerance for the eigenvalues.

See *Application Notes* for more information.

ldz

INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

rwork

REAL for *chpgvx*

DOUBLE PRECISION for *zhpgvx*.

Workspace array, size at least $\max(1, 7n)$.

iwork

INTEGER.

Workspace array, size at least $\max(1, 5n)$.

Output Parameters

ap

On exit, the contents of *ap* are overwritten.

bp

On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as *B*.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',

$m = iu - il + 1$.

w

REAL for *chpgvx*

DOUBLE PRECISION for *zhpgvx*.

Array, size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues in ascending order.

<i>z</i>	<p>COMPLEX for <code>chpgvx</code></p> <p>DOUBLE COMPLEX for <code>zhpgvx</code>.</p> <p>Array <i>z</i>(<i>ldz</i>,*). The second dimension of <i>z</i> must be at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>). The eigenvectors are normalized as follows:</p> <p>if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$;</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p> <p>If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>.</p> <p>Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.</p>
<i>ifail</i>	<p>INTEGER.</p> <p>Array, size at least $\max(1, n)$.</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge.</p> <p>If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.</p> <p>If <i>info</i> > 0, <code>cpptrf/zpptrf</code> and <code>chpevx/zhpevx</code> returned an error code:</p> <p>If <i>info</i> = <i>i</i> ≤ <i>n</i>, <code>chpevx/zhpevx</code> failed to converge, and <i>i</i> eigenvectors failed to converge. Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{?lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{?lamch}('S')$.

?sbgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

```
call ssbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
call dsbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
call sbgv(ab, bb, w [,uplo] [,z] [,info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B;</p> <p>If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B.</p>
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	<p>INTEGER. The number of super- or sub-diagonals in A</p> <p>($ka \geq 0$).</p>
<i>kb</i>	<p>INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).</p>
<i>ab, bb, work</i>	<p>REAL for ssbgv</p> <p>DOUBLE PRECISION for dsbgv</p> <p>Arrays:</p> <p><i>ab</i>(<i>ldab</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>ab</i> must be at least $\max(1, n)$.</p> <p><i>bb</i>(<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by <i>uplo</i>) in band storage format.</p> <p>The second dimension of the array <i>bb</i> must be at least $\max(1, n)$.</p> <p><i>work</i>(*) is a workspace array, dimension at least $\max(1, 3n)$</p>
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The leading dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.</p>

Output Parameters

ab On exit, the contents of *ab* are overwritten.

<i>bb</i>	On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by pbstf/pbstf .
<i>w, z</i>	<p>REAL for <code>ssbgv</code></p> <p>DOUBLE PRECISION for <code>dsbgv</code></p> <p>Arrays:</p> <p>$w(*)$, size at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p> <p>$z(ldz,*)$.</p> <p>The second dimension of z must be at least $\max(1, n)$.</p> <p>If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i-th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.</p> <p>If $jobz = 'N'$, then z is not referenced.</p>
<i>info</i>	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th argument had an illegal value.</p> <p>If $info > 0$, and</p> <p>if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;</p> <p>if $info = n + i$, for $1 \leq i \leq n$, then pbstf/pbstf returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbgv` interface are the following:

<i>ab</i>	Holds the array A of size $(ka+1, n)$.
<i>bb</i>	Holds the array B of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements n .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	<p>Restored based on the presence of the argument z as follows:</p> <p>$jobz = 'V'$, if z is present,</p> <p>$jobz = 'N'$, if z is omitted.</p>

?hbgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

```
call chbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
call zhbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
call hbgv(ab, bb, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here A and B are Hermitian and banded matrices, and matrix B is also positive definite.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
<i>ab, bb, work</i>	COMPLEX for chbgv DOUBLE COMPLEX for zhbgv Arrays: <i>ab(ldab,*)</i> is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb(ldbb,*)</i> is an array containing either upper or lower triangular part of the Hermitian matrix B (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work(*)</i> is a workspace array, dimension at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; must be at least $ka+1$.

<i>ldbb</i>	INTEGER. The leading dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for chbgv DOUBLE PRECISION for zhbqv. Workspace array, size at least $\max(1, 3n)$.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H S$, as returned by pbstf/pbstf .
<i>w</i>	REAL for chbgv DOUBLE PRECISION for zhbqv. Array, size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for chbgv DOUBLE COMPLEX for zhbqv Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized so that $Z^H B Z = I$. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, and if $i \leq n$, the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; if $info = n + i$, for $1 \leq i \leq n$, then pbstf/pbstf returned <i>info</i> = <i>i</i> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *hbqv* interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(ka+1,n)$.
<i>bb</i>	Holds the array <i>B</i> of size $(kb+1,n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

?sbgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

```
call ssbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, iwork,
liwork, info)

call dsbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, iwork,
liwork, info)

call sbgvd(ab, bb, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here *A* and *B* are assumed to be symmetric and banded, and *B* is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If $jobz = 'N'$, then compute eigenvalues only. If $jobz = 'V'$, then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If $uplo = 'U'$, arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ; If $uplo = 'L'$, arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i>

($ka \geq 0$).

kb INTEGER. The number of super- or sub-diagonals in *B* ($kb \geq 0$).

ab, *bb*, *work* REAL for ssbgvd

DOUBLE PRECISION for dsbgvd

Arrays:

ab(*ldab*,*) is an array containing either upper or lower triangular part of the symmetric matrix *A* (as specified by *uplo*) in band storage format.

The second dimension of the array *ab* must be at least $\max(1, n)$.

bb(*lddb*,*) is an array containing either upper or lower triangular part of the symmetric matrix *B* (as specified by *uplo*) in band storage format.

The second dimension of the array *bb* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

ldab INTEGER. The leading dimension of the array *ab*; must be at least $ka+1$.

lddb INTEGER. The leading dimension of the array *bb*; must be at least $kb+1$.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

lwork INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, $lwork \geq 1$;

If *jobz* = 'N' and $n > 1$, $lwork \geq 3n$;

If *jobz* = 'V' and $n > 1$, $lwork \geq 2n^2 + 5n + 1$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If *jobz* = 'N' and $n > 1$, $liwork \geq 1$;

If *jobz* = 'V' and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^T * S$, as returned by pbstf/pbstf .
<i>w, z</i>	<p>REAL for <code>ssbgvd</code></p> <p>DOUBLE PRECISION for <code>dsbgvd</code></p> <p>Arrays:</p> <p><i>w</i>(*), size at least $\max(1, n)$.</p> <p>If <i>info</i> = 0, contains the eigenvalues in ascending order.</p> <p><i>z</i>(<i>ldz</i>,*). The eigenvectors are normalized so that $Z^T * B * Z = I$.</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.</p> <p>If <i>info</i> > 0, and</p> <p>if $i \leq n$, the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero;</p> <p>if $info = n + i$, for $1 \leq i \leq n$, then pbstf/pbstf returned <i>info</i> = <i>i</i> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbgv` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(ka+1,n)$.
<i>bb</i>	Holds the array <i>B</i> of size $(kb+1,n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hbgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

```
call chbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)

call zhbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)

call hbgvd(ab, bb, w [,uplo] [,z] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here *A* and *B* are assumed to be Hermitian and banded, and *B* is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p>

<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, size $\max(1, liwork)$.</p>
<i>liwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>iwork</i>.</p> <p>Constraints:</p> <p>If $n \leq 1, liwork \geq 1$;</p> <p>If $jobz = 'N'$ and $n > 1, liwork \geq 1$;</p> <p>If $jobz = 'V'$ and $n > 1, liwork \geq 5n + 3$.</p> <p>If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H * S$, as returned by pbstf / pbstf .
<i>w</i>	<p>REAL for chbgvd</p> <p>DOUBLE PRECISION for zhbfgvd.</p> <p>Array, size at least $\max(1, n)$.</p> <p>If $info = 0$, contains the eigenvalues in ascending order.</p>
<i>z</i>	<p>COMPLEX for chbgvd</p> <p>DOUBLE COMPLEX for zhbfgvd</p>

Array $z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$.

If $jobz = 'N'$, then z is not referenced.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$rwork(1)$

On exit, if $info = 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.

$iwork(1)$

On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [pbstf/pbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hbgvd` interface are the following:

ab

Holds the array A of size $(ka+1, n)$.

bb

Holds the array B of size $(kb+1, n)$.

w

Holds the vector with the number of elements n .

z

Holds the matrix Z of size (n, n) .

$uplo$

Must be 'U' or 'L'. The default value is 'U'.

$jobz$

Restored based on the presence of the argument z as follows:

$jobz = 'V'$, if z is present,

$jobz = 'N'$, if z is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ ($liwork$ or $lrwork$) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set *lwork* = -1 (*liwork* = -1, *lrwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

```
call ssbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, iwork, ifail, info)
```

```
call dsbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, iwork, ifail, info)
```

```
call sbgvx(ab, bb, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q] [,abstol]
[,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here *A* and *B* are assumed to be symmetric and banded, and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda</i> (<i>i</i>) in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

	<p>If $uplo = 'U'$, arrays ab and bb store the upper triangles of A and B;</p> <p>If $uplo = 'L'$, arrays ab and bb store the lower triangles of A and B.</p>
n	INTEGER. The order of the matrices A and B ($n \geq 0$).
ka	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
kb	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
$ab, bb, work$	<p>REAL for ssbgvx</p> <p>DOUBLE PRECISION for dsbgvx</p> <p>Arrays:</p> <p>$ab(ldab,*)$ is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by $uplo$) in band storage format.</p> <p>The second dimension of the array ab must be at least $\max(1, n)$.</p> <p>$bb(lbdb,*)$ is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by $uplo$) in band storage format.</p> <p>The second dimension of the array bb must be at least $\max(1, n)$.</p> <p>$work(*)$ is a workspace array, size $(7*n)$.</p>
$ldab$	INTEGER. The leading dimension of the array ab ; must be at least $ka+1$.
$ldbb$	INTEGER. The leading dimension of the array bb ; must be at least $kb+1$.
vl, vu	<p>REAL for ssbgvx</p> <p>DOUBLE PRECISION for dsbgvx.</p> <p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or $'I'$, vl and vu are not referenced.</p>
il, iu	<p>INTEGER.</p> <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If $range = 'A'$ or $'V'$, il and iu are not referenced.</p>
$abstol$	<p>REAL for ssbgvx</p> <p>DOUBLE PRECISION for dsbgvx.</p> <p>The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
ldz	INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

ldq INTEGER. The leading dimension of the output array *q*; $ldq < 1$.
If *jobz* = 'V', $ldq < \max(1, n)$.

iwork INTEGER.
Workspace array, size $(5*n)$.

Output Parameters

ab On exit, the contents of *ab* are overwritten.

bb On exit, contains the factor *S* from the split Cholesky factorization $B = S^T * S$, as returned by [pbstf/pbstf](#).

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',
 $m = iu-il+1$.

w, z, q REAL for ssbgvx
DOUBLE PRECISION for dsbgvx
Arrays:
w(*), size at least $\max(1, n)$.
If *info* = 0, contains the eigenvalues in ascending order.
z(*ldz*,*) .
The second dimension of *z* must be at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*). The eigenvectors are normalized so that $Z^T * B * Z = I$.
If *jobz* = 'N', then *z* is not referenced.
q(*ldq*,*) .
The second dimension of *q* must be at least $\max(1, n)$.
If *jobz* = 'V', then *q* contains the *n*-by-*n* matrix used in the reduction of $A * x = \lambda * B * x$ to standard form, that is, $C * x = \lambda * x$ and consequently *C* to tridiagonal form.
If *jobz* = 'N', then *q* is not referenced.

ifail INTEGER.
Array, size (*m*).
If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.
If *jobz* = 'N', then *ifail* is not referenced.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then `pbstf/pbstf` returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `sbgvx` interface are the following:

<code>ab</code>	Holds the array A of size $(ka+1, n)$.
<code>bb</code>	Holds the array B of size $(kb+1, n)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>ifail</code>	Holds the vector with the number of elements n .
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>vl</code>	Default value for this element is $vl = -HUGE(vl)$.
<code>vu</code>	Default value for this element is $vu = HUGE(vl)$.
<code>il</code>	Default value for this argument is $il = 1$.

<code>abstol</code>	Default value for this element is $abstol = 0.0_WP$.
<code>jobz</code>	<p>Restored based on the presence of the argument z as follows:</p> <p>$jobz = 'V'$, if z is present,</p> <p>$jobz = 'N'$, if z is omitted.</p> <p>Note that there will be an error condition if <code>ifail</code> or <code>q</code> is present and z is omitted.</p>
<code>range</code>	<p>Restored based on the presence of arguments vl, vu, il, iu as follows:</p> <p>$range = 'V'$, if one of or both vl and vu are present,</p> <p>$range = 'I'$, if one of or both il and iu are present,</p> <p>$range = 'A'$, if none of vl, vu, il, iu is present,</p> <p>Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.</p>

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon \cdot \|T\|_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 \cdot \text{?lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 \cdot \text{?lamch}('S')$.

?hbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

```
call chbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)

call zhbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu, il, iu,
abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)

call hbgvx(ab, bb, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q] [,abstol]
[,info])
```

Include Files

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A \cdot x = \lambda \cdot B \cdot x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ;

If *uplo* = 'L', arrays *ab* and *bb* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ka INTEGER. The number of super- or sub-diagonals in *A* ($ka \geq 0$).

kb INTEGER. The number of super- or sub-diagonals in *B* ($kb \geq 0$).

ab, bb, work COMPLEX for *chbgvx*
DOUBLE COMPLEX for *zhbgvx*

Arrays:

ab(ldab,)* is an array containing either upper or lower triangular part of the Hermitian matrix *A* (as specified by *uplo*) in band storage format.

The second dimension of the array *ab* must be at least $\max(1, n)$.

bb(lddb,)* is an array containing either upper or lower triangular part of the Hermitian matrix *B* (as specified by *uplo*) in band storage format.

The second dimension of the array *bb* must be at least $\max(1, n)$.

work()* is a workspace array, size at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*; must be at least $ka+1$.

ldbb INTEGER. The leading dimension of the array *bb*; must be at least $kb+1$.

vl, vu REAL for *chbgvx*
DOUBLE PRECISION for *zhbgvx*.

If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *chbgvx*
DOUBLE PRECISION for *zhbgvx*.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', $ldz \geq \max(1, n)$.

ldq INTEGER. The leading dimension of the output array *q*; $ldq \geq 1$. If *jobz* = 'V', $ldq \geq \max(1, n)$.

rwork REAL for chbgvx
DOUBLE PRECISION for zhbgbvx.
Workspace array, size at least $\max(1, 7n)$.

iwork INTEGER.
Workspace array, size at least $\max(1, 5n)$.

Output Parameters

ab On exit, the contents of *ab* are overwritten.

bb On exit, contains the factor *S* from the split Cholesky factorization $B = S^H S$, as returned by [pbstf/pbstf](#).

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',
 $m = iu - il + 1$.

w REAL for chbgvx
DOUBLE PRECISION for zhbgbvx.
Array *w*(*), size at least $\max(1, n)$.
If *info* = 0, contains the eigenvalues in ascending order.

z, q COMPLEX for chbgvx
DOUBLE COMPLEX for zhbgbvx
Arrays:
z(*ldz*,*).
The second dimension of *z* must be at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*). The eigenvectors are normalized so that $Z^H B Z = I$.
If *jobz* = 'N', then *z* is not referenced.
q(*ldq*,*).
The second dimension of *q* must be at least $\max(1, n)$.
If *jobz* = 'V', then *q* contains the *n*-by-*n* matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently *C* to tridiagonal form.
If *jobz* = 'N', then *q* is not referenced.

ifail INTEGER.
Array, size at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th argument had an illegal value.

If *info* > 0, and

if $i \leq n$, the algorithm failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [pbstf/pbstf](#) returned $info = i$ and *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `hbgvx` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(ka+1, n)$.
<i>bb</i>	Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows:

range = 'V', if one of or both *vl* and *vu* are present,

range = 'I', if one of or both *il* and *iu* are present,

range = 'A', if none of *vl*, *vu*, *il*, *iu* is present,

Note that there will be an error condition if one of or both *vl* and *vu* are present and at the same time one of or both *il* and *iu* are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \|T\|_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{lamch}('S')$.

Generalized Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Nonsymmetric Eigenproblems"](#) lists all such driver routines for the FORTRAN 77 interface. The corresponding routine names in the Fortran 95 interface are without the first symbol.

Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

Routine Name	Operation performed
gges	Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.
ggesx	Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.
ggeev	Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.
ggeevx	Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

?gges

Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.

Syntax

```
call sgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas, alphas,
beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)
```

```
call dgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas, alphas,
beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)
```

```
call cgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alpha, beta, vsl,
ldvsl, vsr, ldvsr, work, lwork, rwork, bwork, info)
```

```

Description

The `?gges` routine computes the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vs_l and vs_r) for a pair of n -by- n real/complex nonsymmetric matrices (A,B) . This gives the generalized Schur factorization

$$(A,B) = (vs_l * S * vs_r^H, vs_l * T * vs_r^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of vs_l and vs_r then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

If only the generalized eigenvalues are needed, use the driver `ggev` instead, which is faster.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $alpha / beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ or for both being zero. A pair of matrices (S,T) is in the generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S are "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

The `?gges` routine replaces the deprecated `?gegs` routine.

Input Parameters

<i>jobvsl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed. If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.
<i>jobvsr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed. If <i>jobvsr</i> = 'V', then the right Schur vectors are computed.
<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).
<i>selctg</i>	LOGICAL FUNCTION of three REAL arguments for real flavors.

LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.

selctg must be declared EXTERNAL in the calling subroutine.

If *sort* = 'S', *selctg* is used to select eigenvalues to sort to the top left of the Schur form.

If *sort* = 'N', *selctg* is not referenced.

For real flavors:

An eigenvalue $(\text{alphan}(j) + \text{alphai}(j))/\text{betan}(j)$ is selected if *selctg*(*alphan*(*j*), *alphai*(*j*), *betan*(*j*)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy *selctg*(*alphan*(*j*), *alphai*(*j*), *betan*(*j*)) = .TRUE. after ordering. In this case *info* is set to *n*+2 .

For complex flavors:

An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if *selctg*(*alpha*(*j*), *beta*(*j*)) is true.

Note that a selected complex eigenvalue may no longer satisfy *selctg*(*alpha*(*j*), *beta*(*j*)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case *info* is set to *n*+2 (see *info* below).

n

INTEGER. The order of the matrices *A*, *B*, *vsr*, and *vss* (*n* ≥ 0).

a, *b*, *work*

REAL for *sgges*

DOUBLE PRECISION for *dgges*

COMPLEX for *cgges*

DOUBLE COMPLEX for *zgges*.

Arrays:

a(*lda*,*) is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).

The second dimension of *a* must be at least max(1, *n*).

b(*ldb*,*) is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).

The second dimension of *b* must be at least max(1, *n*).

work is a workspace array, its dimension max(1, *lwork*).

lda

INTEGER. The leading dimension of the array *a*. Must be at least max(1, *n*).

ldb

INTEGER. The leading dimension of the array *b*. Must be at least max(1, *n*).

ldvsr, *ldvss*

INTEGER. The leading dimensions of the output matrices *vsr* and *vss*, respectively. Constraints:

ldvsr ≥ 1. If *jobvsr* = 'V', *ldvsr* ≥ max(1, *n*).

ldvss ≥ 1. If *jobvss* = 'V', *ldvss* ≥ max(1, *n*).

lwork

INTEGER.

The dimension of the array *work*.

$lwork \geq \max(1, 8n+16)$ for real flavors;

$lwork \geq \max(1, 2n)$ for complex flavors.

For good performance, *lwork* must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for *cgges*

DOUBLE PRECISION for *zgges*

Workspace array, size at least $\max(1, 8n)$.

This array is used in complex flavors only.

bwork

LOGICAL.

Workspace array, size at least $\max(1, n)$.

Not referenced if *sort* = 'N'.

Output Parameters

a

On exit, this array has been overwritten by its generalized Schur form *S*.

b

On exit, this array has been overwritten by its generalized Schur form *T*.

sdim

INTEGER.

If *sort* = 'N', *sdim* = 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *selectg* is true.

Note that for real flavors complex conjugate pairs for which *selectg* is true for either eigenvalue count as 2.

alphar, *alphai*

REAL for *sgges*;

DOUBLE PRECISION for *dgges*.

Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cgges*;

DOUBLE COMPLEX for *zgges*.

Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for *sgges*

DOUBLE PRECISION for *dgges*

COMPLEX for *cgges*

DOUBLE COMPLEX for *zgges*.

Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

$\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative.

For complex flavors:

On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alpha}(j)$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) output by `cgges/zgges`. The $\text{beta}(j)$ will be non-negative real.

See also *Application Notes* below.

vs1, vsr

REAL for `sgges`

DOUBLE PRECISION for `dgges`

COMPLEX for `cgges`

DOUBLE COMPLEX for `zgges`.

Arrays:

vs1(*ldvs1*,*), the second dimension of *vs1* must be at least $\max(1, n)$.

If *jobvs1* = 'V', this array will contain the left Schur vectors.

If *jobvs1* = 'N', *vs1* is not referenced.

vsr(*ldvsr*,*), the second dimension of *vsr* must be at least $\max(1, n)$.

If *jobvsr* = 'V', this array will contain the right Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

work(1)

On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$:

the QZ iteration failed. (A, B) is not in Schur form, but $\text{alphar}(j)$, $\text{alphai}(j)$ (for real flavors), or $\text{alpha}(j)$ (for complex flavors), and $\text{beta}(j)$, $j=\text{info}+1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy *selctg* = .TRUE.. This could also be caused due to scaling;

$i = n+3$: reordering failed in `tgseu`.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `gges` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (n, n) .
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (n, n) .
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: <i>jobvsl</i> = 'V', if <i>vsl</i> is present, <i>jobvsl</i> = 'N', if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows: <i>jobvsr</i> = 'V', if <i>vsr</i> is present, <i>jobvsr</i> = 'N', if <i>vsr</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $\alpha(j)/\beta(j)$ and $\alpha_{\text{real}}(j)/\beta(j)$ may easily over- or underflow, and $\beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, α and α_{real} will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and β always less than and usually comparable with $\text{norm}(B)$.

sggesx

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

Syntax

```
call sggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, iwork, liwork,
bwork, info)

call dggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, iwork, liwork,
bwork, info)

call cggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim, alpha,
beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, rwork, iwork, liwork,
bwork, info)

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A,B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T ; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ($rcondv$). The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

<i>jobvsl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed.</p> <p>If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.</p>
<i>jobvsr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed.</p> <p>If <i>jobvsr</i> = 'V', then the right Schur vectors are computed.</p>
<i>sort</i>	<p>CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).</p>
<i>selctg</i>	<p>LOGICAL FUNCTION of three REAL arguments for real flavors.</p> <p>LOGICAL FUNCTION of two COMPLEX arguments for complex flavors.</p> <p><i>selctg</i> must be declared EXTERNAL in the calling subroutine.</p> <p>If <i>sort</i> = 'S', <i>selctg</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>selctg</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue $(\text{alphan}(j) + \text{alphai}(j))/\text{betan}(j)$ is selected if <i>selctg</i>(<i>alphan</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>betan</i>(<i>j</i>)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p>Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alphan</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>betan</i>(<i>j</i>)) = .TRUE. after ordering. In this case <i>info</i> is set to <i>n</i>+2.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue $\text{alpha}(j) / \text{betan}(j)$ is selected if <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>betan</i>(<i>j</i>)) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>betan</i>(<i>j</i>)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> is set to <i>n</i>+2 (see <i>info</i> below).</p>
<i>sense</i>	<p>CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p>

If *sense* = 'N', none are computed;
 If *sense* = 'E', computed for average of selected eigenvalues only;
 If *sense* = 'V', computed for selected deflating subspaces only;
 If *sense* = 'B', computed for both.
 If *sense* is 'E', 'V', or 'B', then *sort* must equal 'S'.

n INTEGER. The order of the matrices *A*, *B*, *vsL*, and *vsR* ($n \geq 0$).

a, *b*, *work* REAL for sggesx
 DOUBLE PRECISION for dggesx
 COMPLEX for cggesx
 DOUBLE COMPLEX for zggesx.

Arrays:

a(*lda*,*) is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).

The second dimension of *a* must be at least $\max(1, n)$.

b(*ldb*,*) is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).

The second dimension of *b* must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of the array *a*.
 Must be at least $\max(1, n)$.

ldb INTEGER. The leading dimension of the array *b*.
 Must be at least $\max(1, n)$.

ldvsl, *ldvsr* INTEGER. The leading dimensions of the output matrices *vsL* and *vsR*, respectively. Constraints:
ldvsl ≥ 1 . If *jobvsl* = 'V', *ldvsl* $\geq \max(1, n)$.
ldvsr ≥ 1 . If *jobvsr* = 'V', *ldvsr* $\geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.

For real flavors:

If *n*=0 then *lwork* ≥ 1 .

If *n*>0 and *sense* = 'N', then *lwork* $\geq \max(8*n, 6*n+16)$.

If *n*>0 and *sense* = 'E', 'V', or 'B', then *lwork* $\geq \max(8*n, 6*n+16, 2*sdim*(n-sdim))$;

For complex flavors:

If *n*=0 then *lwork* ≥ 1 .

If *n*>0 and *sense* = 'N', then *lwork* $\geq \max(1, 2*n)$;

If $n > 0$ and $sense = 'E', 'V',$ or $'B'$, then $lwork \geq \max(1, 2*n, 2*sdim*(n-sdim))$.

Note that $2*sdim*(n-sdim) \leq n*n/2$.

An error is only returned if $lwork < \max(8*n, 6*n+16)$ for real flavors, and $lwork < \max(1, 2*n)$ for complex flavors, but if $sense = 'E', 'V',$ or $'B'$, this may not be large enough.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

rwork

REAL for cggex

DOUBLE PRECISION for zgges

Workspace array, size at least $\max(1, 8n)$.

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, size $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

If $sense = 'N'$, or $n = 0$, then $liwork \geq 1$,

otherwise $liwork \geq (n+6)$ for real flavors, and $liwork \geq (n+2)$ for complex flavors.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

bwork

LOGICAL.

Workspace array, size at least $\max(1, n)$.

Not referenced if $sort = 'N'$.

Output Parameters

a

On exit, this array has been overwritten by its generalized Schur form *S*.

b

On exit, this array has been overwritten by its generalized Schur form *T*.

sdim

INTEGER.

If $sort = 'N'$, $sdim = 0$.

If $sort = 'S'$, *sdim* is equal to the number of eigenvalues (after sorting) for which *selctg* is true.

Note that for real flavors complex conjugate pairs for which *selectg* is true for either eigenvalue count as 2.

alphar, alphas

REAL for *sggesx*;

DOUBLE PRECISION for *dggesx*.

Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cggesx*;

DOUBLE COMPLEX for *zggesx*.

Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for *sggesx*

DOUBLE PRECISION for *dggesx*

COMPLEX for *cggesx*

DOUBLE COMPLEX for *zggesx*.

Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$ will be the generalized eigenvalues.

$\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative.

For complex flavors:

On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$ will be the generalized eigenvalues.

$\text{alpha}(j)$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S,T) output by *cggesx/zggesx*. The $\text{beta}(j)$ will be non-negative real.

See also *Application Notes* below.

vsr, vsr

REAL for *sggesx*

DOUBLE PRECISION for *dggesx*

COMPLEX for *cggesx*

DOUBLE COMPLEX for *zggesx*.

Arrays:

$\text{vsr}(\text{ldvsr},*)$, the second dimension of *vsr* must be at least $\max(1, n)$.

If *jobvsr* = 'V', this array will contain the left Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

$\text{vsr}(\text{ldvsr},*)$, the second dimension of *vsr* must be at least $\max(1, n)$.

If *jobvsr* = 'V', this array will contain the right Schur vectors.

	If <i>jobvsr</i> = 'N', <i>vsr</i> is not referenced.
<i>rconde</i> , <i>rcondv</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Arrays, size (2) each</p> <p>If <i>sense</i> = 'E' or 'B', <i>rconde</i>[0] and <i>rconde</i>[1] contain the reciprocal condition numbers for the average of the selected eigenvalues.</p> <p>Not referenced if <i>sense</i> = 'N' or 'V'.</p> <p>If <i>sense</i> = 'V' or 'B', <i>rcondv</i>(1) and <i>rcondv</i>(2) contain the reciprocal condition numbers for the selected deflating subspaces.</p> <p>Not referenced if <i>sense</i> = 'N' or 'E'.</p>
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>th parameter had an illegal value.</p> <p>If <i>info</i> = <i>i</i>, and</p> <p><i>i</i> ≤ <i>n</i>:</p> <p>the QZ iteration failed. (<i>A</i>, <i>B</i>) is not in Schur form, but <i>alphar</i>(<i>j</i>), <i>alphai</i>(<i>j</i>) (for real flavors), or <i>alpha</i>(<i>j</i>) (for complex flavors), and <i>beta</i>(<i>j</i>), <i>j</i>=<i>info</i>+1, ..., <i>n</i> should be correct.</p> <p><i>i</i> > <i>n</i>: errors that usually indicate LAPACK problems:</p> <p><i>i</i> = <i>n</i>+1: other than QZ iteration failed in ?hgeqz;</p> <p><i>i</i> = <i>n</i>+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy <i>selctg</i> = .TRUE.. This could also be caused due to scaling;</p> <p><i>i</i> = <i>n</i>+3: reordering failed in tgsen.</p>

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *ggesx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.

<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (n, n) .
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (n, n) .
<i>rconde</i>	Holds the vector of length (2).
<i>rcondv</i>	Holds the vector of length (2).
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: $jobvsl = 'V'$, if <i>vsl</i> is present, $jobvsl = 'N'$, if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows: $jobvsr = 'V'$, if <i>vsr</i> is present, $jobvsr = 'N'$, if <i>vsr</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: $sort = 'S'$, if <i>select</i> is present, $sort = 'N'$, if <i>select</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: $sense = 'B'$, if both <i>rconde</i> and <i>rcondv</i> are present, $sense = 'E'$, if <i>rconde</i> is present and <i>rcondv</i> omitted, $sense = 'V'$, if <i>rconde</i> is omitted and <i>rcondv</i> present, $sense = 'N'$, if both <i>rconde</i> and <i>rcondv</i> are omitted.

Note that there will be an error condition if *rconde* or *rcondv* are present and *select* is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set $lwork = -1$ ($liwork = -1$).

If you choose the first option and set any of admissible *lwork* (or *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $alpha_r(j)/beta(j)$ and $alpha_i(j)/beta(j)$ may easily over- or underflow, and $beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, $alpha_r$ and $alpha_i$ will be always less than and usually comparable with $norm(A)$ in magnitude, and $beta$ always less than and usually comparable with $norm(B)$.

?ggev

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

Syntax

```
call sggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphai, beta, vl, ldvl, vr, ldvr,
work, lwork, info)

call dggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphai, beta, vl, ldvl, vr, ldvr,
work, lwork, info)

call cggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr, work,
lwork, rwork, info)

call zggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr, work,
lwork, rwork, info)

call ggev(a, b, alphas, alphai, beta [,vl] [,vr] [,info])
call ggev(a, b, alpha, beta [, vl] [,vr] [,info])
```

Include Files

- mkl.fi, lapack.f90

Description

The ?ggev routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of n -by- n real/complex nonsymmetric matrices (A,B) .

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A*v(j) = \lambda(j)*B*v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H*A = \lambda(j)*u(j)^H*B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

The ?ggev routine replaces the deprecated ?gegv routine.

Input Parameters

<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for sggev

DOUBLE PRECISION for dggev

COMPLEX for cggev

DOUBLE COMPLEX for zggev.

Arrays:

$a(lda,*)$ is an array containing the n -by- n matrix A (first of the pair of matrices).

The second dimension of a must be at least $\max(1, n)$.

$b(l db,*)$ is an array containing the n -by- n matrix B (second of the pair of matrices).

The second dimension of b must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The leading dimension of the array a . Must be at least $\max(1, n)$.

ldb INTEGER. The leading dimension of the array b . Must be at least $\max(1, n)$.

$ldvl, ldvr$ INTEGER. The leading dimensions of the output matrices v_l and v_r , respectively.

Constraints:

$ldvl \geq 1$. If $jobvl = 'V'$, $ldvl \geq \max(1, n)$.

$ldvr \geq 1$. If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.

$lwork$ INTEGER.

The dimension of the array $work$.

$lwork \geq \max(1, 8n+16)$ for real flavors;

$lwork \geq \max(1, 2n)$ for complex flavors.

For good performance, $lwork$ must generally be larger.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

$rwork$ REAL for cggev

DOUBLE PRECISION for zggev

Workspace array, size at least $\max(1, 8n)$.

This array is used in complex flavors only.

Output Parameters

a, b On exit, these arrays have been overwritten.

$alphar, alphai$ REAL for sggev;

DOUBLE PRECISION for dggev.

Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cggev*;

DOUBLE COMPLEX for *zggev*.

Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for *sggev*

DOUBLE PRECISION for *dggev*

COMPLEX for *cggev*

DOUBLE COMPLEX for *zggev*.

Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(\alpha(j) + \alpha_i(j)*i)/\beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

If $\alpha_i(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\alpha_i(j+1)$ negative.

For complex flavors:

On exit, $\alpha(j)/\beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

See also *Application Notes* below.

vl, vr

REAL for *sggev*

DOUBLE PRECISION for *dggev*

COMPLEX for *cggev*

DOUBLE COMPLEX for *zggev*.

Arrays:

vl(*ldvl*,*); the second dimension of *vl* must be at least $\max(1, n)$. Contains the matrix of left generalized eigenvectors *VL*.

If *jobvl* = 'V', the left generalized eigenvectors u_j are stored one after another in the columns of *VL*, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If *jobvl* = 'N', *vl* is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u_j = VL_{*,j}$, the j -th column of *VL*.

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \sqrt{-1}$, $u_j = VL_{*,j} + i*VL_{*,j+1}$ and $u_{j+1} = VL_{*,j} - i*VL_{*,j+1}$.

For complex flavors:

$u_j = VL_{*,j}$, the j -th column of *vl*.

vr(*ldvr*,*); the second dimension of *vr* must be at least $\max(1, n)$. Contains the matrix of right generalized eigenvectors *VR*.

If $jobv = 'V'$, the right generalized eigenvectors v_j are stored one after another in the columns of VR , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobv = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v_j = VR_{*,j}$, the j -th column of VR .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v_j = VR_{*,j} + i*VR_{*,j+1}$ and $v_{j+1} = VR_{*,j} - i*VR_{*,j+1}$.

For complex flavors:

$v_j = VR_{*,j}$, the j -th column of VR .

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but *alphan(j)*, *alphai(j)* (for real flavors), or *alpha(j)* (for complex flavors), and *beta(j)*, $j=info+1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *ggevc* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>alphan</i>	Holds the vector of length n . Used in real flavors only.
<i>alphai</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, n) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, n) .
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows:

$jobvl = 'V'$, if vl is present,

$jobvl = 'N'$, if vl is omitted.

$jobvr$

Restored based on the presence of the argument vr as follows:

$jobvr = 'V'$, if vr is present,

$jobvr = 'N'$, if vr is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $\alpha(j)/\beta(j)$ and $\alpha_{hi}(j)/\beta(j)$ may easily over- or underflow, and $\beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, α and α_{hi} (for real flavors) or α (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and β always less than and usually comparable with $\text{norm}(B)$.

?ggevx

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Syntax

```
call sggevx(balanc, jobvl, jobvr, sense, n, a, lda, b, ldb, alphas, alpha, beta, vl,

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *lscale*, *rscale*, *abnrm*, and *bbnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda * B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H * A = \lambda(j) * u(j)^H * B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>balanc</i>	<p>CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', permute only;</p> <p>If <i>balanc</i> = 'S', scale only;</p> <p>If <i>balanc</i> = 'B', both permute and scale.</p> <p>Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<i>jobvl</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed;</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.</p>
<i>jobvr</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed;</p> <p>If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.</p>
<i>sense</i>	<p>CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for eigenvectors only;</p> <p>If <i>sense</i> = 'B', computed for eigenvalues and eigenvectors.</p>

n	<p>INTEGER. The order of the matrices A, B, vl, and vr ($n \geq 0$).</p>
$a, b, work$	<p>REAL for <code>sggevx</code></p> <p>DOUBLE PRECISION for <code>dggevx</code></p> <p>COMPLEX for <code>cggevx</code></p> <p>DOUBLE COMPLEX for <code>zggevx</code>.</p> <p>Arrays:</p> <p>$a(lda,*)$ is an array containing the n-by-n matrix A (first of the pair of matrices).</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>$b(ldb,*)$ is an array containing the n-by-n matrix B (second of the pair of matrices).</p> <p>The second dimension of b must be at least $\max(1, n)$.</p> <p>$work$ is a workspace array, its dimension $\max(1, lwork)$.</p>
lda	<p>INTEGER. The leading dimension of the array a.</p> <p>Must be at least $\max(1, n)$.</p>
ldb	<p>INTEGER. The leading dimension of the array b.</p> <p>Must be at least $\max(1, n)$.</p>
$ldvl, ldvr$	<p>INTEGER. The leading dimensions of the output matrices vl and vr, respectively.</p> <p>Constraints:</p> <p>$ldvl \geq 1$. If $jobvl = 'V'$, $ldvl \geq \max(1, n)$.</p> <p>$ldvr \geq 1$. If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.</p>
$lwork$	<p>INTEGER.</p> <p>The dimension of the array $work$. $lwork \geq \max(1, 2*n)$;</p> <p>For real flavors:</p> <p>If $balanc = 'S'$, or $'B'$, or $jobvl = 'V'$, or $jobvr = 'V'$, then $lwork \geq \max(1, 6*n)$;</p> <p>if $sense = 'E'$, or $'B'$, then $lwork \geq \max(1, 10*n)$;</p> <p>if $sense = 'V'$, or $'B'$, $lwork \geq (2n^2 + 8*n + 16)$.</p> <p>For complex flavors:</p> <p>if $sense = 'E'$, $lwork \geq \max(1, 4*n)$;</p> <p>if $sense = 'V'$, or $'B'$, $lwork \geq \max(1, 2*n^2 + 2*n)$.</p> <p>If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.</p>
$rwork$	<p>REAL for <code>cggevx</code></p> <p>DOUBLE PRECISION for <code>zggevx</code></p>

Workspace array, size at least $\max(1, 6*n)$ if *balanc* = 'S', or 'B', and at least $\max(1, 2*n)$ otherwise.

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, size at least $(n+6)$ for real flavors and at least $(n+2)$ for complex flavors.

Not referenced if *sense* = 'E'.

bwork

LOGICAL. Workspace array, size at least $\max(1, n)$.

Not referenced if *sense* = 'N'.

Output Parameters

a, b

On exit, these arrays have been overwritten.

If *jobvl* = 'V' or *jobvr* = 'V' or both, then *a* contains the first part of the real Schur form of the "balanced" versions of the input *A* and *B*, and *b* contains its second part.

alphar, alphas

REAL for *sggevx*;

DOUBLE PRECISION for *dggevx*.

Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

alpha

COMPLEX for *cggevx*;

DOUBLE COMPLEX for *zggevx*.

Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta

REAL for *sggevx*

DOUBLE PRECISION for *dggevx*

COMPLEX for *cggevx*

DOUBLE COMPLEX for *zggevx*.

Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

If *alphai*(*j*) is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-st eigenvalues are a complex conjugate pair, with *alphai*(*j*+1) negative.

For complex flavors:

On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

See also *Application Notes* below.

vl, vr

REAL for *sggevx*

DOUBLE PRECISION for dggevx

COMPLEX for cggevx

DOUBLE COMPLEX for zggevx.

Arrays:

$vl(ldvl,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, $u(j) = vl(:, j) + i*vl(:, j+1)$ and $u(j+1) = vl(:, j) - i*vl(:, j+1)$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .

$vr(ldvr,*)$; the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$.

For complex flavors:

$v(j) = vr(:, j)$, the j -th column of vr .

ilo, ihi

INTEGER. ilo and ihi are integer values such that on exit $A_{i,j} = 0$ and $B_{i,j} = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

$lscale, rscale$

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays, size at least $\max(1, n)$ each.

$lscale$ contains details of the permutations and scaling factors applied to the left side of A and B .

If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then

```

lscale(j) = PL(j), for j = 1, ..., ilo-1
= DL(j), for j = ilo, ..., ihi
= PL(j) for j = ihi+1, ..., n.

```

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

rscale contains details of the permutations and scaling factors applied to the right side of *A* and *B*.

If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then

```

rscale(j) = PR(j), for j = 1, ..., ilo-1
= DR(j), for j = ilo, ..., ihi
= PR(j) for j = ihi+1, ..., n.

```

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm, bbnrm

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

The one-norms of the balanced matrices *A* and *B*, respectively.

rconde, rcondv

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Arrays, size at least $\max(1, n)$ each.

If *sense* = 'E', or 'B', *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde(j)*, *rcondv(j)*, and the j -th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected).

If *sense* = 'N', or 'V', *rconde* is not referenced.

If *sense* = 'V', or 'B', *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.

If the eigenvalues cannot be reordered to compute *rcondv(j)rconde[j]*, *rcondv(j)* is set to 0; this can only occur when the true value would be very small anyway.

If *sense* = 'N', or 'E', *rcondv* is not referenced.

work(1)

On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* = i , and

$i \leq n$:

the QZ iteration failed. No eigenvectors have been calculated, but *alphar(j)*, *alpha(j)* (for real flavors), or *alpha(j)* (for complex flavors), and *beta(j)*, $j = \text{info} + 1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n + 1$: other than QZ iteration failed in [hgeqz](#);

$i = n + 2$: error return from [tgevc](#).

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine *ggevx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, n) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, n) .
<i>lscale</i>	Holds the vector of length n .
<i>rscale</i>	Holds the vector of length n .
<i>rconde</i>	Holds the vector of length n .
<i>rcondv</i>	Holds the vector of length n .
<i>balanc</i>	Must be 'N', 'B', or 'P'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: $\text{jobvl} = \text{'V'}$, if <i>vl</i> is present, $\text{jobvl} = \text{'N'}$, if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: $\text{jobvr} = \text{'V'}$, if <i>vr</i> is present, $\text{jobvr} = \text{'N'}$, if <i>vr</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: $\text{sense} = \text{'B'}$, if both <i>rconde</i> and <i>rcondv</i> are present, $\text{sense} = \text{'E'}$, if <i>rconde</i> is present and <i>rcondv</i> omitted, $\text{sense} = \text{'V'}$, if <i>rconde</i> is omitted and <i>rcondv</i> present,

$sense = 'N'$, if both $rconde$ and $rcondv$ are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $alphan(j)/beta(j)$ and $alpha(i)(j)/beta(j)$ may easily over- or underflow, and $beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, $alphan$ and $alpha(i)$ (for real flavors) or $alpha$ (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $beta$ always less than and usually comparable with $\text{norm}(B)$.

Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

The table below summarizes information about the available LAPACK auxiliary routines.

LAPACK Auxiliary Routines

Routine Name	Data Types	Description
?lacgv	c, z	Conjugates a complex vector.
?lacrm	c, z	Multiplies a complex matrix by a square real matrix.
?lacrt	c, z	Performs a linear transformation of a pair of complex vectors.
?laesy	c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix.
?rot	c, z	Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.
?spmv	c, z	Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix
?spr	c, z	Performs the symmetrical rank-1 update of a complex symmetric packed matrix.
?syconv	s, c, d, z	Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.
?symv	c, z	Computes a matrix-vector product for a complex symmetric matrix.
?syr	c, z	Performs the symmetric rank-1 update of a complex symmetric matrix.

Routine Name	Data Types	Description
i?max1	<i>c, z</i>	Finds the index of the vector element whose real part has maximum absolute value.
?sum1	<i>sc, dz</i>	Forms the 1-norm of the complex vector using the true absolute value.
?gbtf2	<i>s, d, c, z</i>	Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.
?gebd2	<i>s, d, c, z</i>	Reduces a general matrix to bidiagonal form using an unblocked algorithm.
?gehd2	<i>s, d, c, z</i>	Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.
?gelq2	<i>s, d, c, z</i>	Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.
?geql2	<i>s, d, c, z</i>	Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2	<i>s, d, c, z</i>	Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2p	<i>s, d, c, z</i>	Computes the QR factorization of a general rectangular matrix with non-negative diagonal elements using an unblocked algorithm.
?geqrt2	<i>s, d, c, z</i>	Computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.
?geqrt3	<i>s, d, c, z</i>	Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.
?gerq2	<i>s, d, c, z</i>	Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.
?gesc2	<i>s, d, c, z</i>	Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2 .
?getc2	<i>s, d, c, z</i>	Computes the LU factorization with complete pivoting of the general n -by- n matrix.
?getf2	<i>s, d, c, z</i>	Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).
?gtts2	<i>s, d, c, z</i>	Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf .
?isnan	<i>s, d,</i>	Tests input for NaN.
?laisnan	<i>s, d,</i>	Tests input for NaN by comparing two arguments for inequality.
?labrd	<i>s, d, c, z</i>	Reduces the first nb rows and columns of a general matrix to a bidiagonal form.
?lacn2	<i>s, d, c, z</i>	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacon	<i>s, d, c, z</i>	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lapy	<i>s, d, c, z</i>	Copies all or part of one two-dimensional array to another.

Routine Name	Data Types	Description
?ladiv	s, d, c, z	Performs complex division in real arithmetic, avoiding unnecessary overflow.
?lae2	s, d	Computes the eigenvalues of a 2-by-2 symmetric matrix.
?laebz	s, d	Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz .
?laed0	s, d, c, z	Used by ?stedc . Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.
?laed1	s, d	Used by sstedc / dstedc . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.
?laed2	s, d	Used by sstedc / dstedc . Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.
?laed3	s, d	Used by sstedc / dstedc . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.
?laed4	s, d	Used by sstedc / dstedc . Finds a single root of the secular equation.
?laed5	s, d	Used by sstedc / dstedc . Solves the 2-by-2 secular equation.
?laed6	s, d	Used by sstedc / dstedc . Computes one Newton step in solution of the secular equation.
?laed7	s, d, c, z	Used by ?stedc . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.
?laed8	s, d, c, z	Used by ?stedc . Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.
?laed9	s, d	Used by sstedc / dstedc . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.
?laeda	s, d	Used by ?stedc . Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.
?laein	s, d, c, z	Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.
?laev2	s, d, c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.
?laexc	s, d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
?lag2	s, d	Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.

Routine Name	Data Types	Description
?lags2	s, d	Computes 2-by-2 orthogonal matrices U , V , and Q , and applies them to matrices A and B such that the rows of the transformed A and B are parallel.
?lagtf	s, d	Computes an LU factorization of a matrix $T-\lambda I$, where T is a general tridiagonal matrix, and λ a scalar, using partial pivoting with row interchanges.
?lagtm	s, d, c, z	Performs a matrix-matrix product of the form $C = \alpha AB + \beta C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.
?lagts	s, d	Solves the system of equations $(T-\lambda I)x = y$ or $(T-\lambda I)^T x = y$, where T is a general tridiagonal matrix and λ a scalar, using the LU factorization computed by ?lagtf .
?lagv2	s, d	Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular.
?lahqr	s, d, c, z	Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.
?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?lahr2	s, d, c, z	Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?laic1	s, d, c, z	Applies one step of incremental condition estimation.
?lakf2	s, d, c, z	Forms a matrix containing Kronecker products between the given matrices.
?lals0	s, d, c, z	Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd .
?lalssa	s, d, c, z	Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd .
?lalstd	s, d, c, z	Uses the singular value decomposition of A to solve the least squares problem.
?lamrg	s, d	Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.
?laneg	s, d	Computes the Sturm count.
?langb	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.
?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Routine Name	Data Types	Description
?langt	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.
?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.
?lansb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.
?lanhbb	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.
?lansp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.
?lanhpb	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.
?lanst/?lanht	s, d/c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.
?lansy	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.
?lanhe	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.
?lantb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.
?lantp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.
?lantr	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.
?lanv2	s, d	Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.
?lapl1	s, d, c, z	Measures the linear dependence of two vectors.
?lapmr	s, d, c, z	Rearranges rows of a matrix as specified by a permutation vector.
?lapmt	s, d, c, z	Performs a forward or backward permutation of the columns of a matrix.
?lapy2	s, d	Returns $\sqrt{x^2+y^2}$.
?lapy3	s, d	Returns $\sqrt{x^2+y^2+z^2}$.

Routine Name	Data Types	Description
?laqgb	<i>s, d, c, z</i>	Scales a general band matrix, using row and column scaling factors computed by ?gbequ .
?laqge	<i>s, d, c, z</i>	Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ .
?laqhb	<i>c, z</i>	Scales a Hermitian band matrix, using scaling factors computed by ?pbequ .
?laqp2	<i>s, d, c, z</i>	Computes a QR factorization with column pivoting of the matrix block.
?laqps	<i>s, d, c, z</i>	Computes a step of QR factorization with column pivoting of a real <i>m</i> -by- <i>n</i> matrix <i>A</i> by using BLAS level 3.
?laqr0	<i>s, d, c, z</i>	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr1	<i>s, d, c, z</i>	Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix <i>H</i> and specified shifts.
?laqr2	<i>s, d, c, z</i>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr3	<i>s, d, c, z</i>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr4	<i>s, d, c, z</i>	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr5	<i>s, d, c, z</i>	Performs a single small-bulge multi-shift QR sweep.
?laqsb	<i>s, d, c, z</i>	Scales a symmetric/Hermitian band matrix, using scaling factors computed by ?pbequ .
?laqsp	<i>s, d, c, z</i>	Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ .
?laqsy	<i>s, d, c, z</i>	Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ .
?laqtr	<i>s, d</i>	Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.
?lar1v	<i>s, d, c, z</i>	Computes the (scaled) <i>r</i> -th column of the inverse of the submatrix in rows <i>b1</i> through <i>bn</i> of the tridiagonal matrix $LDL^T - \lambda I$.
?lar2v	<i>s, d, c, z</i>	Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.
?laran	<i>s, d</i>	Returns a random real number from a uniform distribution.
?larf	<i>s, d, c, z</i>	Applies an elementary reflector to a general rectangular matrix.
?larfb	<i>s, d, c, z</i>	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
?larfg	<i>s, d, c, z</i>	Generates an elementary reflector (Householder matrix).

Routine Name	Data Types	Description
?larfgp	s, d, c, z	Generates an elementary reflector (Householder matrix) with non-negative beta.
?larft	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - \nu t \nu^H$
?larfx	s, d, c, z	Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order ≤ 10 .
?large	s, d, c, z	Pre- and post-multiplies a real general matrix with a random orthogonal matrix.
?larnd	s, d, c, z	Returns a random real number from a uniform or normal distribution.
?largv	s, d, c, z	Generates a vector of plane rotations with real cosines and real/complex sines.
?larnv	s, d, c, z	Returns a vector of random numbers from a uniform or normal distribution.
?laror	s, d, c, z	Pre- or post-multiplies an m -by- n matrix by a random orthogonal/unitary matrix.
?larot	s, d, c, z	Applies a Givens rotation to two adjacent rows or columns.
?larra	s, d	Computes the splitting points with the specified threshold.
?larrb	s, d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrc	s, d	Computes the number of eigenvalues of the symmetric tridiagonal matrix.
?larrd	s, d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
?larre	s, d	Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.
?larrrf	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrrj	s, d	Performs refinement of the initial estimates of the eigenvalues of the matrix T .
?larrrk	s, d	Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.
?larrrr	s, d	Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.
?larrrv	s, d, c, z	Computes the eigenvectors of the tridiagonal matrix $T = LDL^T$ given L , D and the eigenvalues of LDL^T .
?lartg	s, d, c, z	Generates a plane rotation with real cosine and real/complex sine.
?lartgp	s, d	Generates a plane rotation so that the diagonal is nonnegative.
?lartgs	s, d	Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Routine Name	Data Types	Description
<code>?lartv</code>	<code>s, d, c, z</code>	Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.
<code>?laruv</code>	<code>s, d</code>	Returns a vector of n random real numbers from a uniform distribution.
<code>?larz</code>	<code>s, d, c, z</code>	Applies an elementary reflector (as returned by <code>?tzhzrf</code>) to a general matrix.
<code>?larzb</code>	<code>s, d, c, z</code>	Applies a block reflector or its transpose/conjugate-transpose to a general matrix.
<code>?larzt</code>	<code>s, d, c, z</code>	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
<code>?las2</code>	<code>s, d</code>	Computes singular values of a 2-by-2 triangular matrix.
<code>?lascl</code>	<code>s, d, c, z</code>	Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .
<code>?lasd0</code>	<code>s, d</code>	Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by <code>?bdsdc</code> .
<code>?lasd1</code>	<code>s, d</code>	Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by <code>?bdsdc</code> .
<code>?lasd2</code>	<code>s, d</code>	Merges the two sets of singular values together into a single sorted set. Used by <code>?bdsdc</code> .
<code>?lasd3</code>	<code>s, d</code>	Finds all square roots of the roots of the secular equation, as defined by the values in D and Z , and then updates the singular vectors by matrix multiplication. Used by <code>?bdsdc</code> .
<code>?lasd4</code>	<code>s, d</code>	Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by <code>?bdsdc</code> .
<code>?lasd5</code>	<code>s, d</code>	Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by <code>?bdsdc</code> .
<code>?lasd6</code>	<code>s, d</code>	Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by <code>?bdsdc</code> .
<code>?lasd7</code>	<code>s, d</code>	Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by <code>?bdsdc</code> .
<code>?lasd8</code>	<code>s, d</code>	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by <code>?bdsdc</code> .
<code>?lasda</code>	<code>s, d</code>	Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by <code>?bdsdc</code> .
<code>?lasdq</code>	<code>s, d</code>	Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by <code>?bdsdc</code> .
<code>?lasdt</code>	<code>s, d</code>	Creates a tree of subproblems for bidiagonal divide and conquer. Used by <code>?bdsdc</code> .

Routine Name	Data Types	Description
?laset	s, d, c, z	Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.
?lasq1	s, d	Computes the singular values of a real square bidiagonal matrix. Used by ?bdsqr .
?lasq2	s, d	Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the <i>qd</i> Array <i>Z</i> to high relative accuracy. Used by ?bdsqr and ?stegr .
?lasq3	s, d	Checks for deflation, computes a shift and calls <i>dqds</i> . Used by ?bdsqr .
?lasq4	s, d	Computes an approximation to the smallest eigenvalue using values of <i>d</i> from the previous transform. Used by ?bdsqr .
?lasq5	s, d	Computes one <i>dqds</i> transform in ping-pong form. Used by ?bdsqr and ?stegr .
?lasq6	s, d	Computes one <i>dqd</i> transform in ping-pong form. Used by ?bdsqr and ?stegr .
?lasr	s, d, c, z	Applies a sequence of plane rotations to a general rectangular matrix.
?lasrt	s, d	Sorts numbers in increasing or decreasing order.
?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
?lasv2	s, d	Computes the singular value decomposition of a 2-by-2 triangular matrix.
?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
?lasy2	s, d	Solves the Sylvester matrix equation where the matrices are of order 1 or 2.
?lasyf	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.
?lasyf_rook	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the bounded Bunch-Kaufman diagonal pivoting method.
?lahef	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.
?lahef_rook	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method.
?latbs	s, d, c, z	Solves a triangular banded system of equations.
?latdf	s, d, c, z	Uses the LU factorization of the <i>n</i> -by- <i>n</i> matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.
?latm1	s, d, c, z	Computes the entries of a matrix as specified.
?latm2	s, d, c, z	Returns an entry of a random matrix.
?latm3	s, d, c, z	Returns set entry of a random matrix.

Routine Name	Data Types	Description
?latm5	<i>s, d, c, z</i>	Generates matrices involved in the Generalized Sylvester equation.
?latm6	<i>s, d, c, z</i>	Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.
?latme	<i>s, d, c, z</i>	Generates random non-symmetric square matrices with specified eigenvalues.
?latmr	<i>s, d, c, z</i>	Generates random matrices of various types.
?latps	<i>s, d, c, z</i>	Solves a triangular system of equations with the matrix held in packed storage.
?latrd	<i>s, d, c, z</i>	Reduces the first <i>nb</i> rows and columns of a symmetric/Hermitian matrix <i>A</i> to real tridiagonal form by an orthogonal/unitary similarity transformation.
?latrs	<i>s, d, c, z</i>	Solves a triangular system of equations with the scale factor set to prevent overflow.
?latrz	<i>s, d, c, z</i>	Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.
?lauu2	<i>s, d, c, z</i>	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (unblocked algorithm).
?lauum	<i>s, d, c, z</i>	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (blocked algorithm).
?orbdb1/?unbdb1	<i>s, d, c, z</i>	Simultaneously bidiagonalizes the blocks of a tall and skinny matrix with orthonormal columns.
?orbdb2/?unbdb2		
?orbdb3/?unbdb3		
?orbdb4/?unbdb4		
?orbdb5/?unbdb5	<i>s, d, c, z</i>	Orthogonalizes a column vector with respect to the orthonormal basis matrix.
?orbdb6/?unbdb6		
?org2l/?ung2l	<i>s, d/c, z</i>	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a QL factorization determined by ?geqlf (unblocked algorithm).
?org2r/?ung2r	<i>s, d/c, z</i>	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a QR factorization determined by ?geqrf (unblocked algorithm).
?orgl2/?ungl2	<i>s, d/c, z</i>	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from an LQ factorization determined by ?gelqf (unblocked algorithm).
?org2/?ungr2	<i>s, d/c, z</i>	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from an RQ factorization determined by ?gerqf (unblocked algorithm).
?orm2l/?unm2l	<i>s, d/c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).
?orm2r/?unm2r	<i>s, d/c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).

Routine Name	Data Types	Description
?orml2/?unml2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).
?ormr2/?unmr2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by ?gerqf (unblocked algorithm).
?ormr3/?unmr3	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzzrf (unblocked algorithm).
?pbt2f	s, d, c, z	Computes the Cholesky factorization of a symmetric/ Hermitian positive definite band matrix (unblocked algorithm).
?potf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (unblocked algorithm).
?ptts2	s, d, c, z	Solves a tridiagonal system of the form $AX=B$ using the LDL^H factorization computed by ?pttrf .
?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
?syswapr	s, d, c, z	Applies an elementary permutation on the rows and columns of a symmetric matrix.
?heswapr	c, z	Applies an elementary permutation on the rows and columns of a Hermitian matrix.
?sygs2/?hegs2	s, d/c, z	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).
?sytd2/?hetd2	s, d/c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (unblocked algorithm).
?sytf2	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).
?sytf2_rook	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).
?hetf2	c, z	Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).
?hetf2_rook	c, z	Computes the factorization of a complex Hermitian matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).
?tgex2	s, d, c, z	Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.
?tgsy2	s, d, c, z	Solves the generalized Sylvester equation (unblocked algorithm).
?trti2	s, d, c, z	Computes the inverse of a triangular matrix (unblocked algorithm).
clag2z	c→z	Converts a complex single precision matrix to a complex double precision matrix.
dlag2s	d→s	Converts a double precision matrix to a single precision matrix.

Routine Name	Data Types	Description
slag2d	s→d	Converts a single precision matrix to a double precision matrix.
zlag2c	z→c	Converts a complex double precision matrix to a complex single precision matrix.
?larfp	s, d, c, z	Generates a real or complex elementary reflector.
ila?lc	s, d, c, z	Scans a matrix for its last non-zero column.
ila?lr	s, d, c, z	Scans a matrix for its last non-zero row.
?gsvj0	s, d	Pre-processor for the routine ?gesvj .
?gsvj1	s, d	Pre-processor for the routine ?gesvj , applies Jacobi rotations targeting only particular pivots.
?sfrk	s, d	Performs a symmetric rank-k operation for matrix in RFP format.
?hfrk	c, z	Performs a Hermitian rank-k operation for matrix in RFP format.
?tfsm	s, d, c, z	Solves a matrix equation (one operand is a triangular matrix in RFP format).
?lansf	s, d	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix in RFP format.
?lanhf	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian matrix in RFP format.
?tfttp	s, d, c, z	Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).
?tfttr	s, d, c, z	Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR).
?tpqrt2	s, d, c, z	Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.
?tprfb	s, d, c, z	Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.
?tpddf	s, d, c, z	Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).
?tpdtr	s, d, c, z	Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR).
?trddf	s, d, c, z	Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).
?trdtp	s, d, c, z	Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP).
?pstf2	s, d, c, z	Computes the Cholesky factorization with complete pivoting of a real symmetric or complex Hermitian positive semi-definite matrix.
dlat2s	d→s	Converts a double-precision triangular matrix to a single-precision triangular matrix.

Routine Name	Data Types	Description
zlat2c	$z \rightarrow c$	Converts a double complex triangular matrix to a complex triangular matrix.
?lacp2	c, z	Copies all or part of a real two-dimensional array to a complex array.
?la_gbamv	s, d, c, z	Performs a matrix-vector operation to calculate error bounds.
?la_gbrcond	s, d	Estimates the Skeel condition number for a general banded matrix.
?la_gbrcond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{inv}(\text{diag}(c))$ for general banded matrices.
?la_gbrcond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{diag}(x)$ for general banded matrices.
?la_gbrfsx_extended	s, d, c, z	Improves the computed solution to a system of linear equations for general banded matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_gbrpvgrw	s, d, c, z	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a general banded matrix.
?la_geamv	s, d, c, z	Computes a matrix-vector product using a general matrix to calculate error bounds.
?la_gercond	s, d	Estimates the Skeel condition number for a general matrix.
?la_gercond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{inv}(\text{diag}(c))$ for general matrices.
?la_gercond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{diag}(x)$ for general matrices.
?la_gerfsx_extended	s, d	Improves the computed solution to a system of linear equations for general matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_heamv	c, z	Computes a matrix-vector product using a Hermitian indefinite matrix to calculate error bounds.
?la_hercond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{inv}(\text{diag}(c))$ for Hermitian indefinite matrices.
?la_hercond_x	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{diag}(x)$ for Hermitian indefinite matrices.
?la_herfsx_extended	c, z	Improves the computed solution to a system of linear equations for Hermitian indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
?la_lin_berr	s, d, c, z	Computes a component-wise relative backward error.
?la_porcond	s, d	Estimates the Skeel condition number for a symmetric positive-definite matrix.
?la_porcond_c	c, z	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{inv}(\text{diag}(c))$ for Hermitian positive-definite matrices.

Routine Name	Data Types	Description
<code>?la_porcond_x</code>	<code>c, z</code>	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{diag}(x)$ for Hermitian positive-definite matrices.
<code>?la_porfsx_extended</code>	<code>s, d, c, z</code>	Improves the computed solution to a system of linear equations for symmetric or Hermitian positive-definite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
<code>?la_porpvgrw</code>	<code>s, d, c, z</code>	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a symmetric or Hermitian positive-definite matrix.
<code>?laqhe</code>	<code>c, z</code>	Scales a Hermitian matrix.
<code>?laqhp</code>	<code>c, z</code>	Scales a Hermitian matrix stored in packed form.
<code>?larcm</code>	<code>c, z</code>	Copies all or part of a real two-dimensional array to a complex array.
<code>?la_rpvgrw</code>	<code>c, z</code>	Multiplies a square real matrix by a complex matrix.
<code>?larscl2</code>	<code>s, d, c, z</code>	Performs reciprocal diagonal scaling on a vector.
<code>?lascl2</code>	<code>s, d, c, z</code>	Performs diagonal scaling on a vector.
<code>?la_syamv</code>	<code>s, d, c, z</code>	Computes a matrix-vector product using a symmetric indefinite matrix to calculate error bounds.
<code>?la_syrcond</code>	<code>s, d</code>	Estimates the Skeel condition number for a symmetric indefinite matrix.
<code>?la_syrcond_c</code>	<code>c, z</code>	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{inv}(\text{diag}(c))$ for symmetric indefinite matrices.
<code>?la_syrcond_x</code>	<code>c, z</code>	Computes the infinity norm condition number of $\text{op}(A) \cdot \text{diag}(x)$ for symmetric indefinite matrices.
<code>?la_syrfsx_extended</code>	<code>s, d, c, z</code>	Improves the computed solution to a system of linear equations for symmetric indefinite matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution.
<code>?la_syrpvgrw</code>	<code>s, d, c, z</code>	Computes the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$ for a symmetric indefinite matrix.
<code>?la_wwaddw</code>	<code>s, d, c, z</code>	Adds a vector into a doubled-single vector.
<code>mkl_?tpack</code>	<code>s, d, c, z</code>	Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.
<code>mkl_?tpunpack</code>	<code>s, d, c, z</code>	Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.

`?lacgv`

Conjugates a complex vector.

Syntax

```
call clacgv( n, x, incx )
```

```
call zlacgv( n, x, incx )
```

Include Files

- mkl.fi

Description

The routine conjugates a complex vector x of length n and increment $incx$ (see "[Vector Arguments in BLAS](#)" in Appendix B).

Input Parameters

The data types are given for the Fortran interface.

n	INTEGER. The length of the vector x ($n \geq 0$).
x	COMPLEX for <code>clacgv</code> DOUBLE COMPLEX for <code>zlacgv</code> . Array, dimension $(1 + (n-1) * incx)$. Contains the vector of length n to be conjugated.
$incx$	INTEGER. The spacing between successive elements of x .

Output Parameters

x	On exit, overwritten with <code>conjg(x)</code> .
-----	---

?lacrm

Multiplies a complex matrix by a square real matrix.

Syntax

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Include Files

- mkl.fi

Description

The routine performs a simple matrix-matrix multiplication of the form

$$C = A * B,$$

where A is m -by- n and complex, B is n -by- n and real, C is m -by- n and complex.

Input Parameters

m	INTEGER. The number of rows of the matrix A and of the matrix C ($m \geq 0$).
n	INTEGER. The number of columns and rows of the matrix B and the number of columns of the matrix C ($n \geq 0$).
a	COMPLEX for <code>clacrm</code>

	DOUBLE COMPLEX for <code>zlacrm</code>
	Array, DIMENSION(<i>lda</i> , <i>n</i>). Contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> , $lda \geq \max(1, m)$.
<i>b</i>	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code>
	Array, DIMENSION(<i>ldb</i> , <i>n</i>). Contains the <i>n</i> -by- <i>n</i> matrix <i>B</i> .
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> , $ldb \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The leading dimension of the output array <i>c</i> , $ldc \geq \max(1, n)$.
<i>rwork</i>	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code>
	Workspace array, DIMENSION($2*m*n$).

Output Parameters

<i>c</i>	COMPLEX for <code>clacrm</code> DOUBLE COMPLEX for <code>zlacrm</code>
	Array, DIMENSION(<i>ldc</i> , <i>n</i>). Contains the <i>m</i> -by- <i>n</i> matrix <i>C</i> .

?lacrt

Performs a linear transformation of a pair of complex vectors.

Syntax

```
call clacrt( n, cx, incx, cy, incy, c, s )
call zlacrt( n, cx, incx, cy, incy, c, s )
```

Include Files

- `mkl.fi`

Description

The routine performs the following transformation

$$\begin{pmatrix} c & s \\ -s & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \Rightarrow \begin{pmatrix} x \\ y \end{pmatrix},$$

where *c*, *s* are complex scalars and *x*, *y* are complex vectors.

Input Parameters

<i>n</i>	INTEGER. The number of elements in the vectors <i>cx</i> and <i>cy</i> ($n \geq 0$).
----------	--

cx, cy	COMPLEX for <code>clacrt</code> DOUBLE COMPLEX for <code>zlacrt</code> Arrays, dimension (n). Contain input vectors x and y , respectively.
$incx$	INTEGER. The increment between successive elements of cx .
$incy$	INTEGER. The increment between successive elements of cy .
c, s	COMPLEX for <code>clacrt</code> DOUBLE COMPLEX for <code>zlacrt</code> Complex scalars that define the transform matrix

$$\begin{bmatrix} \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \end{bmatrix}$$

Output Parameters

cx	On exit, overwritten with $c*x + s*y$.
cy	On exit, overwritten with $-s*x + c*y$.

?laesy

Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix, and checks that the norm of the matrix of eigenvectors is larger than a threshold value.

Syntax

```
call claesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
call zlaesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
```

Include Files

- `mkl.fi`

Description

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix},$$

provided the norm of the matrix of eigenvectors is larger than some threshold value.

rt1 is the eigenvalue of larger absolute value, and *rt2* of smaller absolute value. If the eigenvectors are computed, then on return (*cs1*, *sn1*) is the unit eigenvector for *rt1*, hence

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -sn1 \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

Input Parameters

a, *b*, *c* COMPLEX for *claesy*
 DOUBLE COMPLEX for *zlaesy*
 Elements of the input matrix.

Output Parameters

rt1, *rt2* COMPLEX for *claesy*
 DOUBLE COMPLEX for *zlaesy*
 Eigenvalues of larger and smaller modulus, respectively.

evscal COMPLEX for *claesy*
 DOUBLE COMPLEX for *zlaesy*
 The complex value by which the eigenvector matrix was scaled to make it orthonormal. If *evscal* is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value *thresh* (set to 0.1E0).

cs1, *sn1* COMPLEX for *claesy*
 DOUBLE COMPLEX for *zlaesy*
 If *evscal* is not zero, then (*cs1*, *sn1*) is the unit right eigenvector for *rt1*.

?rot

Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.

Syntax

```
call crot( n, cx, incx, cy, incy, c, s )
call zrot( n, cx, incx, cy, incy, c, s )
```

Include Files

- `mkl.fi`

Description

The routine applies a plane rotation, where the cosine (*c*) is real and the sine (*s*) is complex, and the vectors *cx* and *cy* are complex. This routine has its real equivalents in BLAS (see [?rot](#) in Chapter 2).

Input Parameters

<i>n</i>	INTEGER. The number of elements in the vectors <i>cx</i> and <i>cy</i> .
<i>cx</i> , <i>cy</i>	REAL for srot DOUBLE PRECISION for drot COMPLEX for crot DOUBLE COMPLEX for zrot Arrays of dimension (<i>n</i>), contain input vectors <i>x</i> and <i>y</i> , respectively.
<i>incx</i>	INTEGER. The increment between successive elements of <i>cx</i> .
<i>incy</i>	INTEGER. The increment between successive elements of <i>cy</i> .
<i>c</i>	REAL for crot DOUBLE PRECISION for zrot
<i>s</i>	REAL for srot DOUBLE PRECISION for drot COMPLEX for crot DOUBLE COMPLEX for zrot Values that define a rotation

$$\begin{bmatrix} c & s \\ -\text{conjg}(s) & c \end{bmatrix}$$

where $c*c + s*\text{conjg}(s) = 1.0$.

Output Parameters

<i>cx</i>	On exit, overwritten with $c*x + s*y$.
<i>cy</i>	On exit, overwritten with $-\text{conjg}(s)*x + c*y$.

?spm

Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix.

Syntax

```
call cspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
call zspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Include Files

- mkl.fi

Description

The `?spmv` routines perform a matrix-vector operation defined as

$$y := \alpha a * x + \beta y,$$

where:

α and β are complex scalars,

x and y are n -element complex vectors

a is an n -by- n complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see `?srmv` in Chapter 2).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix a is supplied in the packed array ap.</p> <p>If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix a is supplied in the array ap.</p> <p>If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix a is supplied in the array ap.</p>
<i>n</i>	<p>INTEGER.</p> <p>Specifies the order of the matrix a.</p> <p>The value of n must be at least zero.</p>
<i>alpha, beta</i>	<p>COMPLEX for <code>cspmv</code></p> <p>DOUBLE COMPLEX for <code>zspmv</code></p> <p>Specify complex scalars α and β. When β is supplied as zero, then y need not be set on input.</p>
<i>ap</i>	<p>COMPLEX for <code>cspmv</code></p> <p>DOUBLE COMPLEX for <code>zspmv</code></p> <p>Array, DIMENSION at least $((n*(n+1))/2)$. Before entry, with <i>uplo</i> = 'U' or 'u', the array ap must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $A(1, 1)$, $ap(2)$ and $ap(3)$ contain $A(1, 2)$ and $A(2, 2)$ respectively, and so on. Before entry, with <i>uplo</i> = 'L' or 'l', the array ap must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1, 1)$, $ap(2)$ and $ap(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.</p>
<i>x</i>	<p>COMPLEX for <code>cspmv</code></p> <p>DOUBLE COMPLEX for <code>zspmv</code></p> <p>Array, DIMENSION at least $(1 + (n-1)*abs(incx))$. Before entry, the incremented array x must contain the n-element vector x.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of x. The value of <i>incx</i> must not be zero.</p>
<i>y</i>	<p>COMPLEX for <code>cspmv</code></p>

DOUBLE COMPLEX for `zspmv`

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array `y` must contain the n -element vector `y`.

`incy`

INTEGER. Specifies the increment for the elements of `y`. The value of `incy` must not be zero.

Output Parameters

`y`

Overwritten by the updated vector `y`.

?spr

Performs the symmetrical rank-1 update of a complex symmetric packed matrix.

Syntax

```
call cspr( uplo, n, alpha, x, incx, ap )
```

```
call zspr( uplo, n, alpha, x, incx, ap )
```

Include Files

- `mk1.fi`

Description

The `?spr` routines perform a matrix-vector operation defined as

$$a := \alpha * x * x^H + a,$$

where:

`alpha` is a complex scalar

`x` is an n -element complex vector

`a` is an n -by- n complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see `?spr` in Chapter 2).

Input Parameters

`uplo`

CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix `a` is supplied in the packed array `ap`, as follows:

If `uplo = 'U'` or `'u'`, the upper triangular part of the matrix `a` is supplied in the array `ap`.

If `uplo = 'L'` or `'l'`, the lower triangular part of the matrix `a` is supplied in the array `ap`.

`n`

INTEGER.

Specifies the order of the matrix `a`.

The value of `n` must be at least zero.

`alpha`

COMPLEX for `cspr`

	DOUBLE COMPLEX for <code>zspr</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <code>cspr</code> DOUBLE COMPLEX for <code>zspr</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>ap</i>	COMPLEX for <code>cspr</code> DOUBLE COMPLEX for <code>zspr</code> Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry, with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>A</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>A</i> (1,2) and <i>A</i> (2,2) respectively, and so on. Before entry, with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2,1) and <i>a</i> (3,1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Output Parameters

<i>ap</i>	With <i>uplo</i> = 'U' or 'u', overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.
-----------	--

?syconv

Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

Syntax

```
call ssyconv( uplo, way, n, a, lda, ipiv, work, info )
call dsyconv( uplo, way, n, a, lda, ipiv, work, info )
call csyconv( uplo, way, n, a, lda, ipiv, work, info )
call zsyconv( uplo, way, n, a, lda, ipiv, work, info )
call syconv( a[,uplo][,way][,ipiv][,info] )
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine converts matrix A , which results from a triangular matrix factorization, into matrices L and D and vice versa. The routine gets non-diagonalized elements of D returned in the workspace and applies or reverses permutation done with the triangular matrix factorization.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the details of the factorization are stored as an upper or lower triangular matrix:</p> <p>If <i>uplo</i> = 'U': the upper triangular, $A = U * D * U^T$.</p> <p>If <i>uplo</i> = 'L': the lower triangular, $A = L * D * L^T$.</p>
<i>way</i>	CHARACTER*1. Must be 'C' or 'R'.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	<p>REAL for <code>ssyconv</code></p> <p>DOUBLE PRECISION for <code>dsyconv</code></p> <p>COMPLEX for <code>csyconv</code></p> <p>DOUBLE COMPLEX for <code>zsyconv</code></p> <p>Array of size <i>lda</i> by <i>n</i>.</p> <p>The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?sytrf</code>.</p>
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ipiv</i>	<p>INTEGER. Array, size at least $\max(1, n)$.</p> <p>Details of the interchanges and the block structure of D, as returned by <code>?sytrf</code>.</p>
<i>work</i>	INTEGER. Workspace array, size at least $\max(1, n)$.

Output Parameters

<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> < 0, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = -1011, memory allocation error occurred.</p>
-------------	---

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `syconv` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'.

<i>way</i>	Must be 'C' or 'R'.
<i>ipiv</i>	Holds the vector of length n .

[?sytrf](#)

?symv

Computes a matrix-vector product for a complex symmetric matrix.

Syntax

```
call csymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
call zsymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Include Files

- `mkl.fi`

Description

The routine performs the matrix-vector operation defined as

$$y := \alpha a * x + \beta y,$$

where:

alpha and *beta* are complex scalars

x and *y* are n -element complex vectors

a is an n -by- n symmetric complex matrix.

These routines have their real equivalents in BLAS (see [?symv](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha, beta</i>	COMPLEX for <i>csymv</i> DOUBLE COMPLEX for <i>zsymv</i> Specify the scalars <i>alpha</i> and <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>a</i>	COMPLEX for <i>csymv</i> DOUBLE COMPLEX for <i>zsymv</i>

Array, DIMENSION (*lda*, *n*). Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *a* must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of *a* is not referenced. Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *a* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. Specifies the leading dimension of *A* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, n)$.

x COMPLEX for csymv
DOUBLE COMPLEX for zsymv

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array *x* must contain the *n*-element vector *x*.

incx INTEGER. Specifies the increment for the elements of *x*. The value of *incx* must not be zero.

y COMPLEX for csymv
DOUBLE COMPLEX for zsymv

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array *y* must contain the *n*-element vector *y*.

incy INTEGER. Specifies the increment for the elements of *y*. The value of *incy* must not be zero.

Output Parameters

y Overwritten by the updated vector *y*.

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```
call csyr( uplo, n, alpha, x, incx, a, lda )
call zsyr( uplo, n, alpha, x, incx, a, lda )
```

Include Files

- mkl.fi

Description

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha * x * x^H + a,$$

where:

- *alpha* is a complex scalar.

- x is an n -element complex vector.
- a is an n -by- n complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array a is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array a is used.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix a. The value of n must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for <i>csyr</i></p> <p>DOUBLE COMPLEX for <i>zsyr</i></p> <p>Specifies the scalar α.</p>
<i>x</i>	<p>COMPLEX for <i>csyr</i></p> <p>DOUBLE COMPLEX for <i>zsyr</i></p> <p>Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n-element vector x.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of x. The value of <i>incx</i> must not be zero.</p>
<i>a</i>	<p>COMPLEX for <i>csyr</i></p> <p>DOUBLE COMPLEX for <i>zsyr</i></p> <p>Array, size (lda, n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n-by-n upper triangular part of the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading n-by-n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.</p>
<i>lda</i>	<p>INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.</p>

Output Parameters

<i>a</i>	<p>With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array a is overwritten by the upper triangular part of the updated matrix.</p> <p>With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array a is overwritten by the lower triangular part of the updated matrix.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> < 0, the i-th parameter had an illegal value.</p> <p>If <i>info</i> = -1011, memory allocation error occurred.</p>

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

```
index = icmax1( n, cx, incx )
```

```
index = izmax1( n, cx, incx )
```

Include Files

- mkl.fi

Description

Given a complex vector *cx*, the *i?max1* functions return the index of the first vector element of maximum absolute value. These functions are based on the BLAS functions *icamax/izamax*, but using the absolute value of components. They are designed for use with *clacon/zlacon*.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the vector <i>cx</i> .
<i>cx</i>	COMPLEX for <i>icmax1</i> DOUBLE COMPLEX for <i>izmax1</i> Array, size at least $(1+(n-1)*abs(incx))$. Contains the input vector.
<i>incx</i>	INTEGER. Specifies the spacing between successive elements of <i>cx</i> .

Output Parameters

<i>index</i>	INTEGER. Index of the vector element of maximum absolute value.
--------------	---

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
res = scsum1( n, cx, incx )
```

```
res = dzsum1( n, cx, incx )
```

Include Files

- mkl.fi

Description

Given a complex vector *cx*, *scsum1/dzsum1* functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on *scasum/dzasum* from Level 1 BLAS, but use the true absolute value and were designed for use with *clacon/zlacon*.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the vector <i>cx</i> .
<i>cx</i>	COMPLEX for <i>scsum1</i> DOUBLE COMPLEX for <i>dzsum1</i> Array, size at least $(1+(n-1)*abs(incx))$. Contains the input vector whose elements will be summed.
<i>incx</i>	INTEGER. Specifies the spacing between successive elements of <i>cx</i> (<i>incx</i> > 0).

Output Parameters

<i>res</i>	REAL for <i>scsum1</i> DOUBLE PRECISION for <i>dzsum1</i> Sum of absolute values.
------------	---

?gbtf2

Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.

Syntax

```
call sgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
```

Include Files

- mkl.fi

Description

The routine forms the *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* with *kl* sub-diagonals and *ku* super-diagonals. The routine uses partial pivoting with row interchanges and implements the unblocked version of the algorithm, calling Level 2 BLAS. See also [?gbtrf](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab</i>	REAL for <i>sgbtf2</i>

DOUBLE PRECISION for `dgbtf2`

COMPLEX for `cgbtf2`

DOUBLE COMPLEX for `zgbtf2`.

Array, DIMENSION (*ldab*,*).

The array *ab* contains the matrix *A* in band storage (see [Matrix Arguments](#)).

The second dimension of *ab* must be at least $\max(1, n)$.

ldab

INTEGER. The leading dimension of the array *ab*.

(*ldab* $\geq 2kl + ku + 1$)

Output Parameters

ab

Overwritten by details of the factorization. The diagonal and *kl* + *ku* super-diagonals of *U* are stored in the first $1 + kl + ku$ rows of *ab*. The multipliers used during the factorization are stored in the next *kl* rows.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, \min(m, n))$.

The pivot indices: row *i* was interchanged with row *ipiv*(*i*).

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, *u*_{*ij*} is 0. The factorization has been completed, but *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

?gebd2

Reduces a general matrix to bidiagonal form using an unblocked algorithm.

Syntax

```
call sgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

```
call dgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

```
call cgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

```
call zgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

Include Files

- `mkl.fi`

Description

The routine reduces a general *m*-by-*n* matrix *A* to upper or lower bidiagonal form *B* by an orthogonal (unitary) transformation: $Q^T A P = B$ (for real flavors) or $Q^H A P = B$ (for complex flavors).

If $m \geq n$, *B* is upper bidiagonal; if $m < n$, *B* is lower bidiagonal.

The routine does not form the matrices *Q* and *P* explicitly, but represents them as products of elementary reflectors. if $m \geq n$,

$Q = H(1) * H(2) * \dots * H(n)$, and $P = G(1) * G(2) * \dots * G(n-1)$

if $m < n$,

$Q = H(1) * H(2) * \dots * H(m-1)$, and $P = G(1) * G(2) * \dots * G(m)$

Each $H(i)$ and $G(i)$ has the form

$H(i) = I - \tau_{uq} v v^T$ and $G(i) = I - \tau_{up} u u^T$ for real flavors, or

$H(i) = I - \tau_{uq} v v^H$ and $G(i) = I - \tau_{up} u u^H$ for complex flavors

where τ_{uq} and τ_{up} are scalars (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`), and v and u are vectors (real for `sgebd2/dgebd2`, complex for `cgebd2/zgebd2`).

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for `sgebd2`
DOUBLE PRECISION for `dgebd2`
COMPLEX for `cgebd2`
DOUBLE COMPLEX for `zgebd2`.

Arrays:

$a(lda, *)$ contains the m -by- n general matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.

$work(*)$ is a workspace array, the dimension of $work$ must be at least $\max(1, m, n)$.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a if $m \geq n$, the diagonal and first super-diagonal of a are overwritten with the upper bidiagonal matrix B . Elements below the diagonal, with the array τ_{uq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the first superdiagonal, with the array τ_{up} , represent the orthogonal/unitary matrix p as a product of elementary reflectors.

if $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . Elements below the first subdiagonal, with the array τ_{uq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the diagonal, with the array τ_{up} , represent the orthogonal/unitary matrix p as a product of elementary reflectors.

d REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains the diagonal elements of the bidiagonal matrix B : $d(i) = a(i, i)$.

<code>e</code>	<p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$.</p> <p>Contains the off-diagonal elements of the bidiagonal matrix B:</p> <p>if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$;</p> <p>if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$.</p>
<code>tauq, tauq</code>	<p>REAL for sgebd2</p> <p>DOUBLE PRECISION for dgebd2</p> <p>COMPLEX for cgebd2</p> <p>DOUBLE COMPLEX for zgebd2.</p> <p>Arrays, DIMENSION at least $\max(1, \min(m, n))$.</p> <p>Contain scalar factors of the elementary reflectors which represent orthogonal/unitary matrices Q and p, respectively.</p>
<code>info</code>	<p>INTEGER.</p> <p>If <code>info</code> = 0, the execution is successful.</p> <p>If <code>info</code> = $-i$, the ith parameter had an illegal value.</p>

?gehd2

Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.

Syntax

```
call sgehd2( n, ilo, ihi, a, lda, tau, work, info )
call dgehd2( n, ilo, ihi, a, lda, tau, work, info )
call cgehd2( n, ilo, ihi, a, lda, tau, work, info )
call zgehd2( n, ilo, ihi, a, lda, tau, work, info )
```

Include Files

- `mk1.fi`

Description

The routine reduces a real/complex general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $Q^T A Q = H$ (for real flavors) or $Q^H A Q = H$ (for complex flavors).

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*.

Input Parameters

<code>n</code>	INTEGER The order of the matrix A ($n \geq 0$).
<code>ilo, ihi</code>	INTEGER. It is assumed that A is already upper triangular in rows and columns $1:ilo - 1$ and $ihi+1:n$.

If A has been output by `?gebal`, then

ilo and ihi must contain the values returned by that routine. Otherwise they should be set to $ilo = 1$ and $ihi = n$. Constraint: $1 \leq ilo \leq ihi \leq \max(1, n)$.

$a, work$

REAL for `sgehd2`

DOUBLE PRECISION for `dgehd2`

COMPLEX for `cgehd2`

DOUBLE COMPLEX for `zgehd2`.

Arrays:

$a(lda, *)$ contains the n -by- n matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.

$work(n)$ is a workspace array.

lda

INTEGER. The leading dimension of a ; at least $\max(1, n)$.

Output Parameters

a

On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H and the elements below the first subdiagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See *Application Notes* below.

τ

REAL for `sgehd2`

DOUBLE PRECISION for `dgehd2`

COMPLEX for `cgehd2`

DOUBLE COMPLEX for `zgehd2`.

Array, DIMENSION at least $\max(1, n-1)$.

Contains the scalar factors of elementary reflectors. See *Application Notes* below.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The matrix Q is represented as a product of $(ihi - ilo)$ elementary reflectors

$$Q = H(ilo) * H(ilo + 1) * \dots * H(ihi - 1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau * v * v^H \text{ for complex flavors}$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$.

On exit, $v(i+2:ihi)$ is stored in $a(i+2:ihi, i)$ and τ in $\tau(i)$.

The contents of a are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ & & v_2 & h & h & h & h \\ & & v_2 & v_3 & h & h & h \\ & & v_2 & v_3 & v_4 & h & h \\ & & & & & & a \end{bmatrix}$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?sgelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgelq2( m, n, a, lda, tau, work, info )
call dgelq2( m, n, a, lda, tau, work, info )
call cgelq2( m, n, a, lda, tau, work, info )
call zgelq2( m, n, a, lda, tau, work, info )
```

Include Files

- mkl.fi

Description

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$$Q = H(k) \dots H(2) H(1) \text{ (or } Q = H(k)^H \dots H(2)^H H(1)^H \text{ for complex flavors), where } k = \min(m, n)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v v^H \text{ for complex flavors,}$$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, $v_{i+1:n}$ (for real functions) and $\text{conjg}(v_{i+1:n})$ (for complex functions) are stored in $a(i, i+1:n)$.

Input Parameters

The data types are given for the Fortran interface.

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgelq2</code> DOUBLE PRECISION for <code>dgelq2</code> COMPLEX for <code>cgelq2</code> DOUBLE COMPLEX for <code>zgelq2</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $work(m)$ is a workspace array.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a	Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array a contain the m -by- $\min(n, m)$ lower trapezoidal matrix L (L is lower triangular if $n \geq m$); the elements above the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors.
τ	REAL for <code>sgelq2</code> DOUBLE PRECISION for <code>dgelq2</code> COMPLEX for <code>cgelq2</code> DOUBLE COMPLEX for <code>zgelq2</code> . Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = -1011$, memory allocation error occurred.

?geql2

Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeql2( m, n, a, lda, tau, work, info )
call dgeql2( m, n, a, lda, tau, work, info )
call cgeql2( m, n, a, lda, tau, work, info )
```

```
call zgeql2( m, n, a, lda, tau, work, info )
```

Include Files

- mkl.fi

Description

The routine computes a *QL* factorization of a real/complex *m*-by-*n* matrix *A* as $A = Q^*L$.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(k)^* \dots ^*H(2)^*H(1)$, where $k = \min(m, n)$.

Each *H*(*i*) has the form

$H(i) = I - \tau v v^T$ for real flavors, or

$H(i) = I - \tau v v^H$ for complex flavors

where τ is a real/complex scalar stored in $\tau(i)$, and *v* is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$.

On exit, $v(1:m-k+i-1)$ is stored in $a(1:m-k+i-1, n-k+i)$.

Input Parameters

<i>m</i>	INTEGER. The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for sgeql2 DOUBLE PRECISION for dgeql2 COMPLEX for cgeql2 DOUBLE COMPLEX for zgeql2. Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (<i>m</i>) is a workspace array.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: on exit, if $m \geq n$, the lower triangle of the subarray <i>a</i> (<i>m</i> - <i>n</i> +1: <i>m</i> , 1: <i>n</i>) contains the <i>n</i> -by- <i>n</i> lower triangular matrix <i>L</i> ; if $m < n$, the elements on and below the (<i>n</i> - <i>m</i>)th superdiagonal contain the <i>m</i> -by- <i>n</i> lower trapezoidal matrix <i>L</i> ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors.
τ	REAL for sgeql2 DOUBLE PRECISION for dgeql2 COMPLEX for cgeql2

DOUBLE COMPLEX for zgeql2.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains scalar factors of the elementary reflectors.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

call sgeqr2(*m*, *n*, *a*, *lda*, *tau*, *work*, *info*)

call dgeqr2(*m*, *n*, *a*, *lda*, *tau*, *work*, *info*)

call cgeqr2(*m*, *n*, *a*, *lda*, *tau*, *work*, *info*)

call zgeqr2(*m*, *n*, *a*, *lda*, *tau*, *work*, *info*)

Include Files

- mkl.fi

Description

The routine computes a QR factorization of a real/complex *m*-by-*n* matrix *A* as $A = Q \cdot R$.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) \cdot H(2) \cdot \dots \cdot H(k)$, where $k = \min(m, n)$

Each *H*(*i*) has the form

$H(i) = I - \tau \cdot v \cdot v^T$ for real flavors, or

$H(i) = I - \tau \cdot v \cdot v^H$ for complex flavors

where *tau* is a real/complex scalar stored in *tau*(*i*), and *v* is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, $v_{i+1:m}$ is stored in *a*(*i*+1:*m*, *i*).

Input Parameters

The data types are given for the Fortran interface.

m INTEGER. The number of rows in the matrix *A* ($m \geq 0$).

n INTEGER. The number of columns in *A* ($n \geq 0$).

a, *work* REAL for sgeqr2

DOUBLE PRECISION for dgeqr2

COMPLEX for cgeqr2

DOUBLE COMPLEX for zgeqr2.

Arrays:

$a(lda, *)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

$work(n)$ is a workspace array.

lda

INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a

Overwritten by the factorization data as follows:

on exit, the elements on and above the diagonal of the array a contain the $\min(n, m)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

tau

REAL for sgeqr2

DOUBLE PRECISION for dgeqr2

COMPLEX for cgeqr2

DOUBLE COMPLEX for zgeqr2.

Array, size at least $\max(1, \min(m, n))$.

Contains scalar factors of the elementary reflectors.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?geqr2p

Computes the QR factorization of a general rectangular matrix with non-negative diagonal elements using an unblocked algorithm.

Syntax

```
call sgeqr2p( m, n, a, lda, tau, work, info )
```

```
call dgeqr2p( m, n, a, lda, tau, work, info )
```

```
call cgeqr2p( m, n, a, lda, tau, work, info )
```

```
call zgeqr2p( m, n, a, lda, tau, work, info )
```

Include Files

Description

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q^*R$. The diagonal entries of R are real and nonnegative.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) * H(2) * \dots * H(k)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v^T$ for real flavors, or

$H(i) = I - \tau v v^H$ for complex flavors

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:m)$ is stored in $a(i+1:m, i)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgeqr2p
DOUBLE PRECISION for d
COMPLEX for cgeqr2p
DOUBLE COMPLEX for zgeqr2p.

Arrays:
 $a(lda, *)$ contains the m -by- n matrix A .
The second dimension of a must be at least $\max(1, n)$.
 $work(n)$ is a workspace array.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
on exit, the elements on and above the diagonal of the array a contain the $\min(n, m)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$).
The diagonal entries of R are real and nonnegative; the elements below the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

tau REAL for sgeqr2p
DOUBLE PRECISION for dgeqr2p
COMPLEX for cgeqr2p
DOUBLE COMPLEX for zgeqr2p.

Array, DIMENSION at least $\max(1, \min(m, n))$.
Contains scalar factors of the elementary reflectors.

info INTEGER.
If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?geqrt2

Computes a QR factorization of a general real or complex matrix using the compact WY representation of Q .

Syntax

```
call sgeqrt2(m, n, a, lda, t, ldt, info)
call dgeqrt2(m, n, a, lda, t, ldt, info)
call cgeqrt2(m, n, a, lda, t, ldt, info)
call zgeqrt2(m, n, a, lda, t, ldt, info)
call geqrt2(a, t, [info])
```

Include Files

- mkl.fi, lapack.f90

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

where v_i represents the vector that defines $H(i)$. The vectors are returned in the lower triangular part of array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$H = I - V^* T^* V^T$ for real flavors, and

$H = I - V^* T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq n$).

<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i>	REAL for <code>sgeqrt2</code> DOUBLE PRECISION for <code>dgeqrt2</code> COMPLEX for <code>cgeqrt2</code> COMPLEX*16 for <code>zgeqrt2</code> . Array, size <i>lda</i> by <i>n</i> . Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldt</i>	INTEGER. The leading dimension of <i>t</i> ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the <i>n</i> -by- <i>n</i> upper triangular matrix <i>R</i> . The elements below the diagonal are the columns of <i>V</i> .
<i>t</i>	REAL for <code>sgeqrt2</code> DOUBLE PRECISION for <code>dgeqrt2</code> COMPLEX for <code>cgeqrt2</code> COMPLEX*16 for <code>zgeqrt2</code> . Array, size (<i>ldt</i> , $\min(m, n)$). The <i>n</i> -by- <i>n</i> upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector <i>T</i> . The elements below the diagonal are not used.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0 and <i>info</i> = - <i>i</i> , the <i>i</i> th argument had an illegal value. If <i>info</i> = -1011, memory allocation error occurred.

?geqrt3

Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.

Syntax

```
call sgeqrt3(m, n, a, lda, t, ldt, info)
call dgeqrt3(m, n, a, lda, t, ldt, info)
call cgeqrt3(m, n, a, lda, t, ldt, info)
call zgeqrt3(m, n, a, lda, t, ldt, info)
call geqrt3(a, t [, info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

```

Include Files

- mkl.fi

Description

The routine computes a RQ factorization of a real/complex m -by- n matrix A as $A = R^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or

$Q = H(1)^H * H(2)^H * \dots * H(k)^H$ for complex flavors

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v^T$ for real flavors, or

$H(i) = I - \tau * v * v^H$ for complex flavors

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$.

On exit, $v(1:n-k+i-1)$ is stored in $a(m-k+i, 1:n-k+i-1)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgerq2
DOUBLE PRECISION for dgerq2
COMPLEX for cgerq2
DOUBLE COMPLEX for zgerq2.

Arrays:
 $a(lda, *)$ contains the m -by- n matrix A .
The second dimension of a must be at least $\max(1, n)$.
 $work(m)$ is a workspace array.

lda INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
on exit, if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ; if $m > n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

τ REAL for sgerq2
DOUBLE PRECISION for dgerq2
COMPLEX for cgerq2
DOUBLE COMPLEX for zgerq2.

Array, DIMENSION at least $\max(1, \min(m, n))$.
Contains scalar factors of the elementary reflectors.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

?gesc2

Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2.

Syntax

```
call sges2( n, a, lda, rhs, ipiv, jpiv, scale )
call dges2( n, a, lda, rhs, ipiv, jpiv, scale )
call cges2( n, a, lda, rhs, ipiv, jpiv, scale )
call zges2( n, a, lda, rhs, ipiv, jpiv, scale )
```

Include Files

- `mkl.fi`

Description

The routine solves a system of linear equations

$$A * X = scale * RHS$$

with a general n -by- n matrix A using the LU factorization with complete pivoting computed by [?getc2](#).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A .
<i>a</i> , <i>rhs</i>	REAL for <code>sges2</code> DOUBLE PRECISION for <code>dges2</code> COMPLEX for <code>cges2</code> DOUBLE COMPLEX for <code>zges2</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the LU part of the factorization of the n -by- n matrix A computed by <code>?getc2</code> : $A = P * L * U * Q.$ The second dimension of <i>a</i> must be at least $\max(1, n)$; <i>rhs</i> (n) contains on entry the right hand side vector for the system of equations.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row i of the matrix has been interchanged with row <i>ipiv</i> (i).
<i>jpiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column j of the matrix has been interchanged with column <i>jpiv</i> (j).

Output Parameters

<i>rhs</i>	On exit, overwritten with the solution vector X .
------------	---

scale REAL for sgesc2/cgesc2
 DOUBLE PRECISION for dgesc2/zgesc2

Contains the scale factor. *scale* is chosen in the range $0 \leq scale \leq 1$ to prevent overflow in the solution.

?getc2

Computes the LU factorization with complete pivoting of the general n -by- n matrix.

Syntax

```
call sgetc2( n, a, lda, ipiv, jpiv, info )
call dgetc2( n, a, lda, ipiv, jpiv, info )
call cgetc2( n, a, lda, ipiv, jpiv, info )
call zgetc2( n, a, lda, ipiv, jpiv, info )
```

Include Files

- mkl.fi

Description

The routine computes an LU factorization with complete pivoting of the n -by- n matrix A . The factorization has the form $A = P * L * U * Q$, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

The LU factorization computed by this routine is used by [?latdf](#) to compute a contribution to the reciprocal Dif-estimate.

Input Parameters

n INTEGER. The order of the matrix A ($n \geq 0$).

a REAL for sgetc2
 DOUBLE PRECISION for dgetc2
 COMPLEX for cgetc2
 DOUBLE COMPLEX for zgetc2.

Array *a*(*lda*,*) contains the n -by- n matrix A to be factored. The second dimension of *a* must be at least $\max(1, n)$;

lda INTEGER. The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

a On exit, the factors L and U from the factorization $A = P * L * U * Q$; the unit diagonal elements of L are not stored. If $U(k, k)$ appears to be less than *smin*, $U(k, k)$ is given the value of *smin*, that is giving a nonsingular perturbed system.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$.

The pivot indices: for $1 \leq i \leq n$, row i of the matrix has been interchanged with row $ipiv(i)$.

jpiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

The pivot indices: for $1 \leq j \leq n$, column j of the matrix has been interchanged with column $jpiv(j)$.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = k > 0$, $U(k, k)$ is likely to produce overflow if we try to solve for x in $A*x = b$. So U is perturbed to avoid the overflow.

?getf2

Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
call sgetf2( m, n, a, lda, ipiv, info )
call dgetf2( m, n, a, lda, ipiv, info )
call cgetf2( m, n, a, lda, ipiv, info )
call zgetf2( m, n, a, lda, ipiv, info )
```

Include Files

- mkl.fi

Description

The routine computes the LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges. The factorization has the form

$$A = P * L * U$$

where p is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

The data types are given for the Fortran interface.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for sgetf2
DOUBLE PRECISION for dgetf2
COMPLEX for cgetf2

DOUBLE COMPLEX for `zgetf2`.

Array, size $(lda, *)$. Contains the matrix A to be factored. The second dimension of a must be at least $\max(1, n)$.

`lda` INTEGER. The leading dimension of a ; at least $\max(1, m)$.

Output Parameters

`a` Overwritten by L and U . The unit diagonal elements of L are not stored.

`ipiv` INTEGER.

Array, size at least $\max(1, \min(m, n))$.

The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$.

`info` INTEGER. If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i > 0`, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

If `info = -1011`, memory allocation error occurred.

?gtts2

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?

`gttrf`.

Syntax

```
call sgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

```
call dgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

```
call cgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

```
call zgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

Include Files

- `mkl.fi`

Description

The routine solves for X one of the following systems of linear equations with multiple right hand sides:

$A^*X = B$, $A^T * X = B$, or $A^H * X = B$ (for complex matrices only), with a tridiagonal matrix A using the LU factorization computed by `?gttrf`.

Input Parameters

`itrans` INTEGER. Must be 0, 1, or 2.

Indicates the form of the equations to be solved:

If `itrans = 0`, then $A^*X = B$ (no transpose).

If $itrans = 1$, then $A^T * X = B$ (transpose).

If $itrans = 2$, then $A^H * X = B$ (conjugate transpose).

n	INTEGER. The order of the matrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right-hand sides, i.e., the number of columns in B ($nrhs \geq 0$).
$dl, d, du, du2, b$	<p>REAL for <code>sgtts2</code></p> <p>DOUBLE PRECISION for <code>dgtts2</code></p> <p>COMPLEX for <code>cgtts2</code></p> <p>DOUBLE COMPLEX for <code>zgtts2</code>.</p> <p>Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $du2(n - 2)$, $b(ldb, nrhs)$.</p> <p>The array dl contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A.</p> <p>The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.</p> <p>The array du contains the $(n - 1)$ elements of the first super-diagonal of U.</p> <p>The array $du2$ contains the $(n - 2)$ elements of the second super-diagonal of U.</p> <p>The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.</p>
ldb	INTEGER. The leading dimension of b ; must be $ldb \geq \max(1, n)$.
$ipiv$	<p>INTEGER.</p> <p>Array, DIMENSION (n).</p> <p>The pivot indices array, as returned by <code>?gttrf</code>.</p>

Output Parameters

b	Overwritten by the solution matrix X .
-----	--

?isnan

Tests input for NaN.

Syntax

```
val = sisnan( sin )
```

```
val = disnan( din )
```

Include Files

- `mk1.fi`

Description

This logical routine returns `.TRUE.` if its argument is NaN, and `.FALSE.` otherwise.

Input Parameters

<i>sin</i>	REAL for <code>sisnan</code> Input to test for NaN.
<i>din</i>	DOUBLE PRECISION for <code>disnan</code> Input to test for NaN.

Output Parameters

<i>val</i>	Logical. Result of the test.
------------	------------------------------

?laisnan

Tests input for NaN.

Syntax

```
val = slaisnan( sin1, sin2 )
val = dlaisnan( din1, din2 )
```

Include Files

- `mkl.fi`

Description

This logical routine checks for NaNs (NaN stands for 'Not A Number') by comparing its two arguments for inequality. NaN is the only floating-point value where `NaN ≠ NaN` returns `.TRUE`. To check for NaNs, pass the same variable as both arguments.

This routine is not for general use. It exists solely to avoid over-optimization in `?isnan`.

Input Parameters

<i>sin1, sin2</i>	REAL for <code>sisnan</code> Two numbers to compare for inequality.
<i>din2, din2</i>	DOUBLE PRECISION for <code>disnan</code> Two numbers to compare for inequality.

Output Parameters

<i>val</i>	Logical. Result of the comparison.
------------	------------------------------------

?labrd

Reduces the first nb rows and columns of a general matrix to a bidiagonal form.

Syntax

```
call slabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call dlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

```
call clabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call zlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

Include Files

- mkl.fi

Description

The routine reduces the first nb rows and columns of a general m -by- n matrix A to upper or lower bidiagonal form by an orthogonal/unitary transformation Q^*A^*P , and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A .

if $m \geq n$, A is reduced to upper bidiagonal form; if $m < n$, to lower bidiagonal form.

The matrices Q and P are represented as products of elementary reflectors: $Q = H(1) * (2) * \dots * H(nb)$, and $P = G(1) * G(2) * \dots * G(nb)$

Each $H(i)$ and $G(i)$ has the form

$$H(i) = I - \tau_{uq} v v' \text{ and } G(i) = I - \tau_{up} u u'$$

where τ_{uq} and τ_{up} are scalars, and v and u are vectors.

The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are needed, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $A := A - V * Y' - X * U'$.

This is an auxiliary routine called by [?gebrd](#).

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
nb	INTEGER. The number of leading rows and columns of A to be reduced.
a	REAL for slabrd DOUBLE PRECISION for dlabrd COMPLEX for clabrd DOUBLE COMPLEX for zlabrd. Array $a(lda,*)$ contains the matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The leading dimension of a ; at least $\max(1, m)$.
ldx	INTEGER. The leading dimension of the output array x ; must be at least $\max(1, m)$.
ldy	INTEGER. The leading dimension of the output array y ; must be at least $\max(1, n)$.

Output Parameters

a	On exit, the first nb rows and columns of the matrix are overwritten; the rest of the array is unchanged.
-----	---

if $m \geq n$, elements on and below the diagonal in the first nb columns, with the array *tauq*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array *taup*, represent the orthogonal/unitary matrix p as a product of elementary reflectors.

if $m < n$, elements below the diagonal in the first nb columns, with the array *tauq*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array *taup*, represent the orthogonal/unitary matrix p as a product of elementary reflectors.

d, *e*

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION (*nb*) each. The array *d* contains the diagonal elements of the first nb rows and columns of the reduced matrix:

$d(i) = a(i, i)$.

The array *e* contains the off-diagonal elements of the first nb rows and columns of the reduced matrix.

tauq, *taup*

REAL for slabrd

DOUBLE PRECISION for dlabrd

COMPLEX for clabrd

DOUBLE COMPLEX for zlabrd.

Arrays, DIMENSION (nb) each. Contain scalar factors of the elementary reflectors which represent the orthogonal/unitary matrices Q and P , respectively.

x, *y*

REAL for slabrd

DOUBLE PRECISION for dlabrd

COMPLEX for clabrd

DOUBLE COMPLEX for zlabrd.

Arrays, dimension $x(ldx, nb)$, $y(ldy, nb)$.

The array *x* contains the m -by- nb matrix X required to update the unreduced part of A .

The array *y* contains the n -by- nb matrix Y required to update the unreduced part of A .

Application Notes

if $m \geq n$, then for the elementary reflectors $H(i)$ and $G(i)$,

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in $a(i:m, i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $a(i, i+1:n)$;

tauq is stored in *tauq*(*i*) and *taup* in *taup*(*i*).

if $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in $a(i+2:m, i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $a(i, i+1:n)$; *tauq* is stored in *tauq*(*i*) and *taup* in *taup*(*i*).

The contents of a on exit are illustrated by the following examples with $nb = 2$:

$m=6, n=5 (m>n)$

$$\begin{bmatrix} 1 & 1 & u_1 & u_1 & u_1 \\ v_1 & 1 & 1 & u_2 & u_2 \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

$m=5, n=6 (m<n)$

$$\begin{bmatrix} 1 & u_1 & u_1 & u_1 & u_1 & u_1 \\ 1 & 1 & u_2 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

?lacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacn2( n, v, x, isgn, est, kase, isave )
call dlacn2( n, v, x, isgn, est, kase, isave )
call clacn2( n, v, x, est, kase, isave )
call zlacn2( n, v, x, est, kase, isave )
```

Include Files

- mkl.fi

Description

The routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 1$).
v, x	REAL for slacn2 DOUBLE PRECISION for dlacn2 COMPLEX for clacn2 DOUBLE COMPLEX for zlacn2. Arrays, size (n) each. v is a workspace array.

x is used as input after an intermediate return.

isgn

INTEGER.

Workspace array, size (n), used with real flavors only.

est

REAL for slacn2/clacn2

DOUBLE PRECISION for dlacn2/zlacn2

On entry with *kase* set to 1 or 2, and *isave*(1) = 1, *est* must be unchanged from the previous call to the routine.

kase

INTEGER.

On the initial call to the routine, *kase* must be set to 0.

isave

INTEGER. Array, size (3).

Contains variables from the previous call to the routine.

Output Parameters

est

An estimate (a lower bound) for $\text{norm}(A)$.

kase

On an intermediate return, *kase* is set to 1 or 2, indicating whether x is overwritten by $A*x$ or A^T*x for real flavors and $A*x$ or A^H*x for complex flavors.

On the final return, *kase* is set to 0.

v

On the final return, $v = A*w$, where $est = \text{norm}(v) / \text{norm}(w)$ (w is not returned).

x

On an intermediate return, x is overwritten by

$A*x$, if *kase* = 1,

A^T*x , if *kase* = 2 (for real flavors),

A^H*x , if *kase* = 2 (for complex flavors),

and the routine must be re-called with all the other parameters unchanged.

isave

This parameter is used to save variables between calls to the routine.

?lacon

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacon( n, v, x, isgn, est, kase )
```

```
call dlacon( n, v, x, isgn, est, kase )
```

```
call clacon( n, v, x, est, kase )
```

```
call zlacon( n, v, x, est, kase )
```

Include Files

- `mk1.fi`

Description

The routine estimates the 1-norm of a square, real/complex matrix A . Reverse communication is used for evaluating matrix-vector products.

WARNING

The `?lacon` routine is not thread-safe. It is deprecated and retained for the backward compatibility only. Use the thread-safe `?lacn2` routine instead.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 1$).
v, x	REAL for <code>slacon</code> DOUBLE PRECISION for <code>dlacon</code> COMPLEX for <code>clacon</code> DOUBLE COMPLEX for <code>zlacon</code> . Arrays, DIMENSION (n) each. v is a workspace array. x is used as input after an intermediate return.
$isgn$	INTEGER. Workspace array, DIMENSION (n), used with real flavors only.
est	REAL for <code>slacon/clacon</code> DOUBLE PRECISION for <code>dlacon/zlacon</code> An estimate that with $kase=1$ or 2 should be unchanged from the previous call to <code>?lacon</code> .
$kase$	INTEGER. On the initial call to <code>?lacon</code> , $kase$ should be 0 .

Output Parameters

est	REAL for <code>slacon/clacon</code> DOUBLE PRECISION for <code>dlacon/zlacon</code> An estimate (a lower bound) for $\text{norm}(A)$.
$kase$	On an intermediate return, $kase$ will be 1 or 2 , indicating whether x should be overwritten by $A*x$ or A^T*x for real flavors and $A*x$ or A^H*x for complex flavors. On the final return from <code>?lacon</code> , $kase$ will again be 0 .
v	On the final return, $v = A*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (w is not returned).

x On an intermediate return, x should be overwritten by

$A*x$, if $kase = 1$,

A^T*x , if $kase = 2$ (for real flavors),

A^H*x , if $kase = 2$ (for complex flavors),

and `?lacon` must be re-called with all the other parameters unchanged.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call slacpy( uplo, m, n, a, lda, b, ldb )
call dlacpy( uplo, m, n, a, lda, b, ldb )
call clacpy( uplo, m, n, a, lda, b, ldb )
call zlacpy( uplo, m, n, a, lda, b, ldb )
```

Include Files

- `mkl.fi`

Description

The routine copies all or part of a two-dimensional matrix A to another matrix B .

Input Parameters

The data types are given for the Fortran interface.

$uplo$	<p>CHARACTER*1.</p> <p>Specifies the part of the matrix A to be copied to B.</p> <p>If $uplo = 'U'$, the upper triangular part of A;</p> <p>if $uplo = 'L'$, the lower triangular part of A.</p> <p>Otherwise, all of the matrix A is copied.</p>
m	<p>INTEGER. The number of rows in the matrix A ($m \geq 0$).</p>
n	<p>INTEGER. The number of columns in A ($n \geq 0$).</p>
a	<p>REAL for <code>slacpy</code></p> <p>DOUBLE PRECISION for <code>dlacpy</code></p> <p>COMPLEX for <code>clacpy</code></p> <p>DOUBLE COMPLEX for <code>zlacpy</code>.</p> <p>Array $a(lda,*)$, contains the m-by-n matrix A.</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>If $uplo = 'U'$, only the upper triangle or trapezoid is accessed; if $uplo = 'L'$, only the lower triangle or trapezoid is accessed.</p>

lda INTEGER. The leading dimension of *a*; $lda \geq \max(1, m)$.

ldb INTEGER. The leading dimension of the output array *b*; $ldb \geq \max(1, m)$.

Output Parameters

b REAL for slacpy
 DOUBLE PRECISION for dlacpy
 COMPLEX for clacpy
 DOUBLE COMPLEX for zlacpy.
 Array *b*(*ldb*,*), contains the *m*-by-*n* matrix *B*.
 The second dimension of *b* must be at least $\max(1, n)$.
 On exit, $B = A$ in the locations specified by *uplo*.

?ladiv

Performs complex division in real arithmetic, avoiding unnecessary overflow.

Syntax

```
call sladiv( a, b, c, d, p, q )
call dladiv( a, b, c, d, p, q )
res = cladiv( x, y )
res = zladiv( x, y )
```

Include Files

- mkl.fi

Description

The routines *sladiv*/*dladiv* perform complex division in real arithmetic as

$$p + iq = \frac{a + ib}{c + id}$$

Complex functions *cladiv*/*zladiv* compute the result as

$res = x/y$,

where *x* and *y* are complex. The computation of *x* / *y* will not overflow on an intermediary step unless the results overflows.

The algorithm used is due to [\[Baudin12\]](#).

Input Parameters

a, b, c, d REAL for sladiv
 DOUBLE PRECISION for dladiv

The scalars a , b , c , and d in the above expression (for real flavors only).

x, y COMPLEX for cladiv
 DOUBLE COMPLEX for zladiv

The complex scalars x and y (for complex flavors only).

Output Parameters

p, q REAL for sladiv
 DOUBLE PRECISION for dladiv

The scalars p and q in the above expression (for real flavors only).

res COMPLEX for cladiv
 DOUBLE COMPLEX for zladiv
 Contains the result of division x / y .

?lae2

Computes the eigenvalues of a 2-by-2 symmetric matrix.

Syntax

```
call sla2( a, b, c, rt1, rt2 )
call dla2( a, b, c, rt1, rt2 )
```

Include Files

- mkl.fi

Description

The routines sla2/dla2 compute the eigenvalues of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix}$$

On return, $rt1$ is the eigenvalue of larger absolute value, and $rt2$ is the eigenvalue of smaller absolute value.

Input Parameters

a, b, c REAL for sla2
 DOUBLE PRECISION for dla2

The elements a , b , and c of the 2-by-2 matrix above.

Output Parameters

$rt1, rt2$ REAL for sla2

DOUBLE PRECISION for dlae2

The computed eigenvalues of larger and smaller absolute value, respectively.

Application Notes

rt1 is accurate to a few ulps barring over/underflow. *rt2* may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute *rt2* accurately in all cases.

Overflow is possible only if *rt1* is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds

underflow_threshold / *macheps*.

?laebz

Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz.

Syntax

```
call slaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d, e, e2,
nval, ab, c, mout, nab, work, iwork, info )
```

```
call dlaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d, e, e2,
nval, ab, c, mout, nab, work, iwork, info )
```

Include Files

- mkl.fi

Description

The routine ?laebz contains the iteration loops which compute and use the function $n(w)$, which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w . It performs a choice of two types of loops:

- | | |
|-------------|---|
| <i>ijob</i> | =1, followed by |
| <i>ijob</i> | =2: It takes as input a list of intervals and returns a list of sufficiently small intervals whose union contains the same eigenvalues as the union of the original intervals. The input intervals are $(ab(j,1), ab(j,2)]$, $j=1, \dots, minp$. The output interval $(ab(j,1), ab(j,2)]$ will contain eigenvalues $nab(j, 1)+1, \dots, nab(j,2)$, where $1 \leq j \leq mout$. |
| <i>ijob</i> | =3: It performs a binary search in each input interval $(ab(j,1), ab(j,2)]$ for a point $w(j)$ such that $n(w(j))=nval(j)$, and uses $c(j)$ as the starting point of the search. If such a $w(j)$ is found, then on output $ab(j,1)=ab(j,2)=w$. If no such $w(j)$ is found, then on output $(ab(j,1), ab(j,2)]$ will be a small interval containing the point where $n(w)$ jumps through $nval(j)$, unless that point lies outside the initial interval. |

Note that the intervals are in all cases half-open intervals, that is, of the form $(a, b]$, which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than $\text{overflow}^{1/2} * \text{overflow}^{1/4}$ in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

NOTE

In general, the arguments are not checked for unreasonable values.

Input Parameters

<i>ijob</i>	<p>INTEGER. Specifies what is to be done:</p> <ul style="list-style-type: none"> = 1: Compute <i>nab</i> for the initial intervals. = 2: Perform bisection iteration to find eigenvalues of <i>T</i>. = 3: Perform bisection iteration to invert $n(w)$, i.e., to find a point which has a specified number of eigenvalues of <i>T</i> to its left. Other values will cause ?laebz to return with <i>info</i>=-1.
<i>nitmax</i>	<p>INTEGER. The maximum number of "levels" of bisection to be performed, i.e., an interval of width <i>W</i> will not be made smaller than $2^{-nitmax * W}$. If not all intervals have converged after <i>nitmax</i> iterations, then <i>info</i> is set to the number of non-converged intervals.</p>
<i>n</i>	<p>INTEGER. The dimension <i>n</i> of the tridiagonal matrix <i>T</i>. It must be at least 1.</p>
<i>mmax</i>	<p>INTEGER. The maximum number of intervals. If more than <i>mmax</i> intervals are generated, then ?laebz will quit with <i>info</i>=<i>mmax</i>+1.</p>
<i>minp</i>	<p>INTEGER. The initial number of intervals. It may not be greater than <i>mmax</i>.</p>
<i>nbmin</i>	<p>INTEGER. The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.</p>
<i>abstol</i>	<p>REAL for slaebz DOUBLE PRECISION for dlaebz.</p> <p>The minimum (absolute) width of an interval. When an interval is narrower than <i>abstol</i>, or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.</p>
<i>reltol</i>	<p>REAL for slaebz DOUBLE PRECISION for dlaebz.</p> <p>The minimum relative width of an interval. When an interval is narrower than <i>abstol</i>, or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least <i>radix*machineepsilon</i>.</p>
<i>pivmin</i>	<p>REAL for slaebz DOUBLE PRECISION for dlaebz.</p>

The minimum absolute value of a "pivot" in the Sturm sequence loop. This value **must** be at least $(\max |e(j)|^2) * \text{safe_min}$ and at least *safe_min*, where *safe_min* is at least the smallest number that can divide one without overflow.

d, e, e2

REAL for slaebz

DOUBLE PRECISION for dlaebz.

Arrays, dimension (*n*) each. The array *d* contains the diagonal elements of the tridiagonal matrix *T*.

The array *e* contains the off-diagonal elements of the tridiagonal matrix *T* in positions 1 through *n*-1. *e(n)* is arbitrary.

The array *e2* contains the squares of the off-diagonal elements of the tridiagonal matrix *T*. *e2(n)* is ignored.

nval

INTEGER.

Array, dimension (*minp*).

If *ijob*=1 or 2, not referenced.

If *ijob*=3, the desired values of *n(w)*.

ab

REAL for slaebz

DOUBLE PRECISION for dlaebz.

Array, dimension (*mmax*,2) The endpoints of the intervals. *ab(j,1)* is *a(j)*, the left endpoint of the *j*-th interval, and *ab(j,2)* is *b(j)*, the right endpoint of the *j*-th interval.

c

REAL for slaebz

DOUBLE PRECISION for dlaebz.

Array, dimension (*mmax*)

If *ijob*=1, ignored.

If *ijob*=2, workspace.

If *ijob*=3, then on input *c(j)* should be initialized to the first search point in the binary search.

nab

INTEGER.

Array, dimension (*mmax*,2)

If *ijob*=2, then on input, *nab(i,j)* should be set. It must satisfy the condition:

$n(ab(i,1)) \leq nab(i,1) \leq nab(i,2) \leq n(ab(i,2))$, which means that in interval *i* only eigenvalues $nab(i,1)+1, \dots, nab(i,2)$ are considered. Usually, $nab(i,j) = n(ab(i,j))$, from a previous call to ?laebz with *ijob*=1.

If *ijob*=3, normally, *nab* should be set to some distinctive value(s) before ?laebz is called.

work

REAL for slaebz

DOUBLE PRECISION for dlaebz.

Workspace array, dimension (*mmax*).

iwork

INTEGER.

Workspace array, dimension (*mmax*).

Output Parameters

nval

The elements of *nval* will be reordered to correspond with the intervals in *ab*. Thus, *nval(j)* on output will not, in general be the same as *nval(j)* on input, but it will correspond with the interval (*ab(j,1)*, *ab(j,2)*] on output.

ab

The input intervals will, in general, be modified, split, and reordered by the calculation.

mout

INTEGER.

If *ijob*=1, the number of eigenvalues in the intervals.

If *ijob*=2 or 3, the number of intervals output.

If *ijob*=3, *mout* will equal *minp*.

nab

If *ijob*=1, then on output *nab(i,j)* will be set to *N(ab(i,j))*.

If *ijob*=2, then on output, *nab(i,j)* will contain $\max(na(k, \min(nb(k), N(ab(i,j))))$, where *k* is the index of the input interval that the output interval (*ab(j,1)*, *ab(j,2)*] came from, and *na(k)* and *nb(k)* are the input values of *nab(k,1)* and *nab(k,2)*.

If *ijob*=3, then on output, *nab(i,j)* contains *N(ab(i,j))*, unless *N(w) > nval(i)* for all search points *w*, in which case *nab(i,1)* will not be modified, i.e., the output value will be the same as the input value (modulo reorderings, see *nval* and *ab*), or unless *N(w) < nval(i)* for all search points *w*, in which case *nab(i,2)* will not be modified.

info

INTEGER.

If *info* = 0 - all intervals converged

If *info* = 1--*mmax* - the last *info* interval did not converge.

If *info* = *mmax*+1 - more than *mmax* intervals were generated

Application Notes

This routine is intended to be called only by other LAPACK routines, thus the interface is less user-friendly. It is intended for two purposes:

(a) finding eigenvalues. In this case, *?laebz* should have one or more initial intervals set up in *ab*, and *?laebz* should be called with *ijob*=1. This sets up *nab*, and also counts the eigenvalues. Intervals with no eigenvalues would usually be thrown out at this point. Also, if not all the eigenvalues in an interval *i* are desired, *nab(i,1)* can be increased or *nab(i,2)* decreased. For example, set *nab(i,1)=nab(i,2)-1* to get the largest eigenvalue. *?laebz* is then called with *ijob*=2 and *mmax* no smaller than the value of *mout* returned by the call with *ijob*=1. After this (*ijob*=2) call, eigenvalues *nab(i,1)+1* through *nab(i,2)* are approximately *ab(i,1)* (or *ab(i,2)*) to the tolerance specified by *abstol* and *reltol*.

(b) finding an interval (*a'*, *b'*] containing eigenvalues *w(f)*, ..., *w(l)*. In this case, start with a Gershgorin interval (*a*, *b*). Set up *ab* to contain 2 search intervals, both initially (*a*, *b*). One *nval* element should contain *f-1* and the other should contain *l*, while *c* should contain *a* and *b*, respectively. *nab(i,1)* should be -1 and

$nab(i,2)$ should be $n+1$, to flag an error if the desired interval does not lie in (a,b) . `?laebz` is then called with $ijob=3$. On exit, if $w(f-1) < w(f)$, then one of the intervals -- j -- will have $ab(j,1)=ab(j,2)$ and $nab(j,1)=nab(j,2)=f-1$, while if, to the specified tolerance, $w(f-k)=\dots=w(f+r)$, $k > 0$ and $r \geq 0$, then the interval will have $n(ab(j,1))=nab(j,1)=f-k$ and $n(ab(j,2))=nab(j,2)=f+r$. The cases $w(1) < w(1+1)$ and $w(l-r)=\dots=w(l+k)$ are handled similarly.

?laed0

Used by ?stedc. Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.

Syntax

```
call slaed0( icipq, qsiz, n, d, e, q, ldq, qstore, ldqs, work, iwork, info )
call dlaed0( icipq, qsiz, n, d, e, q, ldq, qstore, ldqs, work, iwork, info )
call claed0( qsiz, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
call zlaed0( qsiz, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
```

Include Files

- mkl.fi

Description

Real flavors of this routine compute all eigenvalues and (optionally) corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Complex flavors `claed0/zlaed0` compute all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Input Parameters

<i>icipq</i>	<p>INTEGER. Used with real flavors only.</p> <p>If <i>icipq</i> = 0, compute eigenvalues only.</p> <p>If <i>icipq</i> = 1, compute eigenvectors of original dense symmetric matrix also.</p> <p>On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.</p> <p>If <i>icipq</i> = 2, compute eigenvalues and eigenvectors of the tridiagonal matrix.</p>
<i>qsiz</i>	<p>INTEGER.</p> <p>The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icipq</i> = 1).</p>
<i>n</i>	<p>INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).</p>
<i>d, e, rwork</i>	<p>REAL for single-precision flavors</p> <p>DOUBLE PRECISION for double-precision flavors. Arrays:</p>

$d(*)$ contains the main diagonal of the tridiagonal matrix. The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of the tridiagonal matrix. The dimension of e must be at least $\max(1, n-1)$.

$rwork(*)$ is a workspace array used in complex flavors only. The dimension of $rwork$ must be at least $(1 + 3n + 2n\log_2(n) + 3n^2)$, where $\log_2(n) =$ smallest integer k such that $2^k \geq n$.

$q, qstore$

REAL for slaed0

DOUBLE PRECISION for dlaed0

COMPLEX for claed0

DOUBLE COMPLEX for zlaed0.

Arrays: $q(ldq, *)$, $qstore(ldqs, *)$. The second dimension of these arrays must be at least $\max(1, n)$.

For real flavors:

If $icompg = 0$, array q is not referenced.

If $icompg = 1$, on entry, q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time.

If $icompg = 2$, on entry, q will be the identity matrix. The array $qstore$ is a workspace array referenced only when $icompg = 1$. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

For complex flavors:

On entry, q must contain an $qsiz$ -by- n matrix whose columns are unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix. The array $qstore$ is a workspace array used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

ldq

INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.

$ldqs$

INTEGER. The leading dimension of the array $qstore$; $ldqs \geq \max(1, n)$.

$work$

REAL for slaed0

DOUBLE PRECISION for dlaed0.

Workspace array, used in real flavors only.

If $icompg = 0$ or 1 , the dimension of $work$ must be at least $(1 + 3n + 2n\log_2(n) + 3n^2)$, where $\log_2(n) =$ smallest integer k such that $2^k \geq n$.

If $icompg = 2$, the dimension of $work$ must be at least $(4n + n^2)$.

$iwork$

INTEGER.

Workspace array.

For real flavors, if $icompg = 0$ or 1 , and for complex flavors, the dimension of $iwork$ must be at least $(6 + 6n + 5n\log_2(n))$.

For real flavors, if $icompg = 2$, the dimension of $iwork$ must be at least $(3+5n)$.

Output Parameters

d	On exit, contains eigenvalues in ascending order.
e	On exit, the array is destroyed.
q	If $icompg = 2$, on exit, q contains the eigenvectors of the tridiagonal matrix.
$info$	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = i > 0$, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $i/(n+1)$ through $\text{mod}(i, n+1)$.</p>

?laed1

Used by `sstedc/dstedc`. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.

Syntax

```
call slaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
call dlaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
```

Include Files

- `mkl.fi`

Description

The routine `?laed1` computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. `?laed7` handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \text{rho} * Z * Z^T) * Q^T(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^T(\text{out})$$

where $Z = Q^T u$, u is a vector of length n with ones in the cutpnt and $(\text{cutpnt}+1)$ -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?laed2`.

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine `?laed4` (as called by `?laed3`). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>d</i> , <i>q</i> , <i>work</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1. Arrays: <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> , *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $(4n+n^2)$.
<i>ldq</i>	INTEGER. The leading dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1. The subdiagonal entry used to create the rank-1 modification. This parameter can be modified by ?laed2, where it is input/output.
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq cutpnt \leq n/2$.
<i>iwork</i>	INTEGER. Workspace array, dimension $(4n)$.

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.
<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.
<i>indxq</i>	On exit, contains the permutation which will reintegrate the subproblems back into sorted order, that is, <i>d</i> (<i>indxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed2

Used by sstedc/dstedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.

Syntax

```
call slaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc, indxp,
coltyp, info )
```

```
call dlaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc, indxp,
coltyp, info )
```

Include Files

- mkl.fi

Description

The routine ?laed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

k	INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation ($0 \leq k \leq n$).
n	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
$n1$	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
d, q, z	REAL for slaed2 DOUBLE PRECISION for dlaed2. Arrays: $d(*)$ contains the eigenvalues of the two submatrices to be combined. The dimension of d must be at least $\max(1, n)$. $q(ldq, *)$ contains the eigenvectors of the two submatrices in the two square blocks with corners at $(1,1)$, $(n1,n1)$ and $(n1+1,n1+1)$, (n,n) . The second dimension of q must be at least $\max(1, n)$. $z(*)$ contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).
ldq	INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.
$indxq$	INTEGER. Array, dimension (n) . On entry, the permutation which separately sorts the two subproblems in d into ascending order. Note that elements in the second half of this permutation must first have $n1$ added to their values.
ρ	REAL for slaed2

DOUBLE PRECISION for `dlaed2`.

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.

indx, indxp

INTEGER.

Workspace arrays, dimension (*n*) each. Array *indx* contains the permutation used to sort the contents of *dlaeda* into ascending order.

Array *indxp* contains the permutation used to place deflated values of *d* at the end of the array.

indxp(1:*k*) points to the nondeflated *d*-values and *indxp*(*k*+1:*n*) points to the deflated eigenvalues.

coltyp

INTEGER.

Workspace array, dimension (*n*).

During execution, a label which will indicate which of the following types a column in the *q2* matrix is:

- 1 : non-zero in the upper half only;
- 2 : dense;
- 3 : non-zero in the lower half only;
- 4 : deflated.

Output Parameters

d

On exit, *d* contains the trailing (*n-k*) updated eigenvalues (those which were deflated) sorted into increasing order.

q

On exit, *q* contains the trailing (*n-k*) updated eigenvectors (those which were deflated) in its last *n-k* columns.

z

On exit, *z* content is destroyed by the updating process.

indxq

Destroyed on exit.

rho

On exit, *rho* has been modified to the value required by `?laed3`.

dlaeda, w, q2

REAL for `slaed2`

DOUBLE PRECISION for `dlaed2`.

Arrays: *dlaeda*(*n*), *w*(*n*), *q2*(*n*²+(*n*-*n*₁)²).

The array *dlaeda* contains a copy of the first *k* eigenvalues which is used by `?laed3` to form the secular equation.

The array *w* contains the first *k* values of the final deflation-altered *z*-vector which is passed to `?laed3`.

The array *q2* contains a copy of the first *k* eigenvectors which is used by `?laed3` in a matrix multiply (`sgemm/dgemm`) to solve for the new eigenvectors.

indxc

INTEGER. Array, dimension (*n*).

The permutation used to arrange the columns of the deflated q matrix into three groups: the first group contains non-zero elements only at and above $n1$, the second contains non-zero elements only below $n1$, and the third is dense.

coltyp

On exit, *coltyp*(i) is the number of columns of type i , for $i=1$ to 4 only (see the definition of types in the description of *coltyp* in *Input Parameters*).

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

?laed3

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.

Syntax

```
call slaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
```

```
call dlaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
```

Include Files

- mkl.fi

Description

The routine ?laed3 finds the roots of the secular equation, as defined by the values in d , w , and ρ , between 1 and k .

It makes the appropriate calls to ?laed4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the k -by- k system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but none are known.

Input Parameters

k INTEGER. The number of terms in the rational function to be solved by ?laed4 ($k \geq 0$).

n INTEGER. The number of rows and columns in the q matrix. $n \geq k$ (deflation may result in $n > k$).

$n1$ INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.

q REAL for slaed3
DOUBLE PRECISION for dlaed3.

Array $q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. Initially, the first k columns of this array are used as workspace.

ldq INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.

rho REAL for slaed3

DOUBLE PRECISION for dlaed3.

The value of the parameter in the rank one update equation. $rho \geq 0$ required.

dlamda, q2, w REAL for slaed3

DOUBLE PRECISION for dlaed3.

Arrays: $dlamda(k)$, $q2(ldq2, *)$, $w(k)$.

The first k elements of the array *dlamda* contain the old roots of the deflated updating problem. These are the poles of the secular equation.

The first k columns of the array *q2* contain the non-deflated eigenvectors for the split problem. The second dimension of *q2* must be at least $\max(1, n)$.

The first k elements of the array *w* contain the components of the deflation-adjusted updating vector.

indx INTEGER. Array, dimension (n).

The permutation used to arrange the columns of the deflated q matrix into three groups (see ?1aed2).

The rows of the eigenvectors found by ?1aed4 must be likewise permuted before the matrix multiply can take place.

ctot INTEGER. Array, dimension (4).

A count of the total number of the various types of columns in q , as described in *indx*. The fourth column type is any column which has been deflated.

s REAL for slaed3

DOUBLE PRECISION for dlaed3.

Workspace array, dimension $(n1+1)*k$.

Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

Output Parameters

d REAL for slaed3

DOUBLE PRECISION for dlaed3.

Array, dimension at least $\max(1, n)$.

$d(i)$ contains the updated eigenvalues for $1 \leq i \leq k$.

q On exit, the columns 1 to k of q contain the updated eigenvectors.

<i>dlambda</i>	May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.
<i>w</i>	Destroyed on exit.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed4

Used by sstedc/dstedc. Finds a single root of the secular equation.

Syntax

```
call slaed4( n, i, d, z, delta, rho, dlam, info )
call dlaed4( n, i, d, z, delta, rho, dlam, info )
```

Include Files

- mkl.fi

Description

This routine computes the *i*-th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array *d*, and that

$D(i) < D(j)$ for $i < j$

and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$\text{diag}(D) + \rho * Z * \text{transpose}(Z)$.

where we assume the Euclidean norm of *Z* is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

<i>n</i>	INTEGER. The length of all arrays.
<i>i</i>	INTEGER. The index of the eigenvalue to be computed; $1 \leq i \leq n$.
<i>d</i> , <i>z</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4 Arrays, dimension (<i>n</i>) each. The array <i>d</i> contains the original eigenvalues. It is assumed that they are in order, $d(i) < d(j)$ for $i < j$. The array <i>z</i> contains the components of the updating vector <i>Z</i> .
<i>rho</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4

The scalar in the symmetric updating formula.

Output Parameters

<i>delta</i>	<p>REAL for slaed4</p> <p>DOUBLE PRECISION for dlaed4</p> <p>Array, dimension (<i>n</i>).</p> <p>If $n \neq 1$, <i>delta</i> contains $(d(j) - \lambda_i)$ in its <i>j</i>-th component. If $n = 1$, then $delta(1) = 1$. The vector <i>delta</i> contains the information necessary to construct the eigenvectors.</p>
<i>diam</i>	<p>REAL for slaed4</p> <p>DOUBLE PRECISION for dlaed4</p> <p>The computed λ_i, the <i>i</i>-th updated eigenvalue.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = 1, the updating process failed.</p>

?laed5

Used by sstedc/dstedc. Solves the 2-by-2 secular equation.

Syntax

```
call slaed5( i, d, z, delta, rho, diam )
call dlaed5( i, d, z, delta, rho, diam )
```

Include Files

- mkl.fi

Description

The routine computes the *i*-th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(D) + \rho * Z * \text{transpose}(Z)$.

The diagonal elements in the array *D* are assumed to satisfy

$D(i) < D(j)$ for $i < j$.

We also assume $\rho > 0$ and that the Euclidean norm of the vector *Z* is one.

Input Parameters

<i>i</i>	<p>INTEGER. The index of the eigenvalue to be computed;</p> <p>$1 \leq i \leq 2$.</p>
<i>d, z</i>	<p>REAL for slaed5</p> <p>DOUBLE PRECISION for dlaed5</p>

Arrays, dimension (2) each. The array d contains the original eigenvalues. It is assumed that $d(1) < d(2)$.

The array z contains the components of the updating vector.

rho

REAL for slaed5

DOUBLE PRECISION for dlaed5

The scalar in the symmetric updating formula.

Output Parameters

delta

REAL for slaed5

DOUBLE PRECISION for dlaed5

Array, dimension (2).

The vector *delta* contains the information necessary to construct the eigenvectors.

diam

REAL for slaed5

DOUBLE PRECISION for dlaed5

The computed λ_i , the i -th updated eigenvalue.

?laed6

Used by sstedc/dstedc. Computes one Newton step in solution of the secular equation.

Syntax

```
call slaed6( kniter, orgati, rho, d, z, finit, tau, info )
```

```
call dlaed6( kniter, orgati, rho, d, z, finit, tau, info )
```

Include Files

- mkl.fi

Description

The routine computes the positive or negative root (closest to the origin) of

$$f(x) = \rho + \frac{z(1)}{d(1) - x} + \frac{z(2)}{d(2) - x} + \frac{z(3)}{d(3) - x}$$

It is assumed that if *orgati* = .TRUE. the root is between $d(2)$ and $d(3)$; otherwise it is between $d(1)$ and $d(2)$. This routine is called by ?laed4 when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Input Parameters

kniter

INTEGER.

Refer to ?laed4 for its significance.

orgati

LOGICAL.

If *orgati* = .TRUE., the needed root is between $d(2)$ and $d(3)$; otherwise it is between $d(1)$ and $d(2)$. See ?laed4 for further details.

rho

REAL for slaed6

DOUBLE PRECISION for dlaed6

Refer to the equation for $f(x)$ above.

d, z

REAL for slaed6

DOUBLE PRECISION for dlaed6

Arrays, dimension (3) each.

The array *d* satisfies $d(1) < d(2) < d(3)$.

Each of the elements in the array *z* must be positive.

finit

REAL for slaed6

DOUBLE PRECISION for dlaed6

The value of $f(x)$ at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

Output Parameters

tau

REAL for slaed6

DOUBLE PRECISION for dlaed6

The root of the equation for $f(x)$.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = 1, failure to converge.

?laed7

Used by ?stedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.

Syntax

```
call slaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho, cutpnt,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info )
```

```
call dlaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho, cutpnt,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info )
```

```
call claed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq, qstore,
qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info )
```

```
call zlaed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq, qstore,

```

Include Files

- `mk1.fi`

Description

The routine `?laed7` computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric/Hermitian matrix that has been reduced to tridiagonal form. For real flavors, `slaed1/dlaed1` handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \rho * Z * Z^T) * Q^T(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^T(\text{out}) \text{ for real flavors, or}$$

$$T = Q(\text{in}) * (D(\text{in}) + \rho * Z * Z^H) * Q^H(\text{in}) = Q(\text{out}) * D(\text{out}) * Q^H(\text{out}) \text{ for complex flavors}$$

where $Z = Q^T * u$ for real flavors and $Z = Q^H * u$ for complex flavors, u is a vector of length n with ones in the `cutpnt` and `(cutpnt + 1)`-th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `slaed8/dlaed8` (for real flavors) or by the routine `slaed2/dlaed2` (for complex flavors).

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine `?laed4` (as called by `?laed9` or `?laed3`). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<code>icompq</code>	INTEGER. Used with real flavors only. If <code>icompq = 0</code> , compute eigenvalues only. If <code>icompq = 1</code> , compute eigenvectors of original dense symmetric matrix also. On entry, the array q must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
<code>n</code>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<code>cutpnt</code>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq \text{cutpnt} \leq n$.
<code>qsiz</code>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <code>icompq = 1</code>).
<code>tlvls</code>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<code>curlvl</code>	INTEGER. The current level in the overall merge routine, $0 \leq \text{curlvl} \leq \text{tlvls}$.

<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>d</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension at least $\max(1, n)$. Array <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix.
<i>q, work</i>	REAL for slaed7 DOUBLE PRECISION for dlaed7 COMPLEX for claed7 DOUBLE COMPLEX for zlaed7. Arrays: <i>q</i> (<i>ldq</i> , *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $(3n+2*qsiz*n)$ for real flavors and at least $(qsiz*n)$ for complex flavors.
<i>ldq</i>	INTEGER. The leading dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). Contains the permutation that separately sorts the two sub-problems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed7 /claed7 DOUBLE PRECISION for dlaed7/zlaed7. The subdiagonal element used to create the rank-1 modification.
<i>qstore</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension (n^2+1) . Serves also as output parameter. Stores eigenvectors of submatrices encountered during divide and conquer, packed together. <i>qptr</i> points to beginning of the submatrices.
<i>qptr</i>	INTEGER. Array, dimension $(n+2)$. Serves also as output parameter. List of indices pointing to beginning of submatrices stored in <i>qstore</i> . The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.
<i>prmptr, perm, givptr</i>	INTEGER. Arrays, dimension $(n \log_2 n)$ each. The array <i>prmptr</i> (*) contains a list of pointers which indicate where in <i>perm</i> a level's permutation is stored. <i>prmptr</i> (<i>i</i> +1) - <i>prmptr</i> (<i>i</i>) indicates the size of the permutation and also the size of the full, non-deflated problem. The array <i>perm</i> (*) contains the permutations (from deflation and sorting) to be applied to each eigenblock. This parameter can be modified by ? laed8, where it is output.

The array *givptr*(*) contains a list of pointers which indicate where in *givcol* a level's Givens rotations are stored. *givptr*(*i*+1) - *givptr*(*i*) indicates the number of Givens rotations.

givcol

INTEGER. Array, dimension $(2, n \log_2 n)$.

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

givnum

REAL for slaed7/claed7

DOUBLE PRECISION for dlaed7/zlaed7.

Array, dimension $(2, n \log_2 n)$.

Each number indicates the *S* value to be used in the corresponding Givens rotation.

iwork

INTEGER.

Workspace array, dimension $(4n)$.

rwork

REAL for claed7

DOUBLE PRECISION for zlaed7.

Workspace array, dimension $(3n+2q_{siz}*n)$. Used in complex flavors only.

Output Parameters

d

On exit, contains the eigenvalues of the repaired matrix.

q

On exit, *q* contains the eigenvectors of the repaired tridiagonal matrix.

indxq

INTEGER. Array, dimension (n) .

Contains the permutation that reintegrates the subproblems back into a sorted order, that is,

$d(\text{indxq}(i = 1, n))$ will be in the ascending order.

rho

This parameter can be modified by ?1aed8, where it is input/output.

prmptr, *perm*, *givptr*

INTEGER. Arrays, dimension $(n \log_2 n)$ each.

The array *prmptr* contains an updated list of pointers.

The array *perm* contains an updated permutation.

The array *givptr* contains an updated list of pointers.

givcol

This parameter can be modified by ?1aed8, where it is output.

givnum

This parameter can be modified by ?1aed8, where it is output.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, an eigenvalue did not converge.

?laed8

Used by ?stedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.

Syntax

```
call slaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda, q2, ldq2,
w, perm, givptr, givcol, givnum, indxp, indx, info )

call dlaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda, q2, ldq2,
w, perm, givptr, givcol, givnum, indxp, indx, info )

call claed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp, indx,
indxq, perm, givptr, givcol, givnum, info )

call zlaed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp, indx,
indxq, perm, givptr, givcol, givnum, info )
```

Include Files

- mkl.fi

Description

The routine merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

<i>icompg</i>	<p>INTEGER. Used with real flavors only.</p> <p>If <i>icompg</i> = 0, compute eigenvalues only.</p> <p>If <i>icompg</i> = 1, compute eigenvectors of original dense symmetric matrix also.</p> <p>On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.</p>
<i>n</i>	<p>INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).</p>
<i>cutpnt</i>	<p>INTEGER. The location of the last eigenvalue in the leading sub-matrix.</p> <p>$\min(1, n) \leq \text{cutpnt} \leq n$.</p>
<i>qsiz</i>	<p>INTEGER.</p> <p>The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompg</i> = 1).</p>
<i>d</i> , <i>z</i>	<p>REAL for slaed8/claed8</p> <p>DOUBLE PRECISION for dlaed8/zlaed8.</p> <p>Arrays, dimension at least $\max(1, n)$ each. The array <i>d</i>(*) contains the eigenvalues of the two submatrices to be combined.</p>

On entry, $z(*)$ contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of z are destroyed by the updating process.

q REAL for slaed8
DOUBLE PRECISION for dlaed8
COMPLEX for claed8
DOUBLE COMPLEX for zlaed8.

Array

$q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. On entry, q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems.

For real flavors, If $icompq = 0$, q is not referenced.

ldq INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.

$ldq2$ INTEGER. The leading dimension of the output array $q2$; $ldq2 \geq \max(1, n)$.

$indxq$ INTEGER. Array, dimension (n) .

The permutation that separately sorts the two sub-problems in d into ascending order. Note that elements in the second half of this permutation must first have $cutpnt$ added to their values in order to be accurate.

ρ REAL for slaed8/claed8
DOUBLE PRECISION for dlaed8/zlaed8.

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.

Output Parameters

k INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation.

d On exit, contains the trailing $(n-k)$ updated eigenvalues (those which were deflated) sorted into increasing order.

z On exit, the updating process destroys the contents of z .

q On exit, q contains the trailing $(n-k)$ updated eigenvectors (those which were deflated) in its last $(n-k)$ columns.

$indxq$ INTEGER. Array, dimension (n) .

The permutation of merged eigenvalues set.

ρ On exit, ρ has been modified to the value required by ?laed3.

$d\lambda, w$ REAL for slaed8/claed8
DOUBLE PRECISION for dlaed8/zlaed8.

Arrays, dimension (n) each. The array *dlamda*(*) contains a copy of the first k eigenvalues which will be used by ?laed3 to form the secular equation.

The array *w*(*) will hold the first k values of the final deflation-altered z -vector and will be passed to ?laed3.

q2

REAL for slaed8
DOUBLE PRECISION for dlaed8
COMPLEX for claed8
DOUBLE COMPLEX for zlaed8.

Array

q2(*ldq2*, *). The second dimension of *q2* must be at least $\max(1, n)$.

Contains a copy of the first k eigenvectors which will be used by slaed7/dlaed7 in a matrix multiply (sgemm/dgemm) to update the new eigenvectors. For real flavors, If *icompg* = 0, *q2* is not referenced.

indxp, *indx*

INTEGER. Workspace arrays, dimension (n) each.

The array *indxp*(*) will contain the permutation used to place deflated values of d at the end of the array. On output, *indxp*(1: k) points to the nondeflated d -values and *indxp*($k+1:n$) points to the deflated eigenvalues.

The array *indx*(*) will contain the permutation used to sort the contents of d into ascending order.

perm

INTEGER. Array, dimension (n).

Contains the permutations (from deflation and sorting) to be applied to each eigenblock.

givptr

INTEGER. Contains the number of Givens rotations which took place in this subproblem.

givcol

INTEGER. Array, dimension (2, n).

Each pair of numbers indicates a pair of columns to take place in a Givens rotation.

givnum

REAL for slaed8/claed8
DOUBLE PRECISION for dlaed8/zlaed8.

Array, dimension (2, n).

Each number indicates the S value to be used in the corresponding Givens rotation.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

?laed9

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.

Syntax

```
call slaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
```

```
call dlaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
```

Include Files

- mkl.fi

Description

The routine finds the roots of the secular equation, as defined by the values in d , z , and ρ , between $kstart$ and $kstop$. It makes the appropriate calls to `slaed4/dlaed4` and then stores the new matrix of eigenvectors for use in calculating the next level of z vectors.

Input Parameters

k	INTEGER. The number of terms in the rational function to be solved by <code>slaed4/dlaed4</code> ($k \geq 0$).
$kstart, kstop$	INTEGER. The updated eigenvalues $\lambda(i)$, $kstart \leq i \leq kstop$ are to be computed. $1 \leq kstart \leq kstop \leq k$.
n	INTEGER. The number of rows and columns in the Q matrix. $n \geq k$ (deflation may result in $n > k$).
q	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> . Workspace array, dimension $(ldq, *)$. The second dimension of q must be at least $\max(1, n)$.
ldq	INTEGER. The leading dimension of the array q ; $ldq \geq \max(1, n)$.
ρ	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
$dlamda, w$	REAL for <code>slaed9</code> DOUBLE PRECISION for <code>dlaed9</code> Arrays, dimension (k) each. The first k elements of the array $dlamda(*)$ contain the old roots of the deflated updating problem. These are the poles of the secular equation.

The first k elements of the array $w(*)$ contain the components of the deflation-adjusted updating vector.

lds INTEGER. The leading dimension of the output array s ; $lds \geq \max(1, k)$.

Output Parameters

d REAL for slaed9
DOUBLE PRECISION for dlaed9
Array, dimension (n). Elements in $d(i)$ are not referenced for $1 \leq i < kstart$ or $kstop < i \leq n$.

s REAL for slaed9
DOUBLE PRECISION for dlaed9.
Array, dimension ($lds, *$) .
The second dimension of s must be at least $\max(1, k)$. Will contain the eigenvectors of the repaired matrix which will be stored for subsequent z vector calculation and multiplied by the previously accumulated eigenvectors to update the system.

dlamda On exit, the value is modified to make sure all $d\lambda(i) - d\lambda(j)$ can be computed with high relative accuracy, barring overflow and underflow.

w Destroyed on exit.

info INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the eigenvalue did not converge.

?laeda

Used by ?stedc. Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.

Syntax

```
call slaeda( n, tlvs, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum, q, qptr,
z, ztemp, info )
```

```
call dlaeda( n, tlvs, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum, q, qptr,
z, ztemp, info )
```

Include Files

- mkl.fi

Description

The routine ?laeda computes the Z vector corresponding to the merge step in the $curlvl$ -th step of the merge process with $tlvs$ steps for the $curpbm$ -th problem.

Input Parameters

<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>tlvls</i>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<i>curlvl</i>	INTEGER. The current level in the overall merge routine, $0 \leq \text{curlvl} \leq \text{tlvls}$.
<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>prmptr, perm, givptr</i>	<p>INTEGER. Arrays, dimension $(n \log_2 n)$ each.</p> <p>The array <i>prmptr</i>(*) contains a list of pointers which indicate where in <i>perm</i> a level's permutation is stored. <i>prmptr</i>(i+1) - <i>prmptr</i>(i) indicates the size of the permutation and also the size of the full, non-deflated problem.</p> <p>The array <i>perm</i>(*) contains the permutations (from deflation and sorting) to be applied to each eigenblock.</p> <p>The array <i>givptr</i>(*) contains a list of pointers which indicate where in <i>givcol</i> a level's Givens rotations are stored. <i>givptr</i>(i+1) - <i>givptr</i>(i) indicates the number of Givens rotations.</p>
<i>givcol</i>	<p>INTEGER. Array, dimension $(2, n \log_2 n)$.</p> <p>Each pair of numbers indicates a pair of columns to take place in a Givens rotation.</p>
<i>givnum</i>	<p>REAL for slaeda</p> <p>DOUBLE PRECISION for dlaeda.</p> <p>Array, dimension $(2, n \log_2 n)$.</p> <p>Each number indicates the <i>S</i> value to be used in the corresponding Givens rotation.</p>
<i>q</i>	<p>REAL for slaeda</p> <p>DOUBLE PRECISION for dlaeda.</p> <p>Array, dimension (n^2).</p> <p>Contains the square eigenblocks from previous levels, the starting positions for blocks are given by <i>qptr</i>.</p>
<i>qptr</i>	<p>INTEGER. Array, dimension $(n+2)$. Contains a list of pointers which indicate where in <i>q</i> an eigenblock is stored. $\text{sqrt}(\text{qptr}(i+1) - \text{qptr}(i))$ indicates the size of the block.</p>
<i>ztemp</i>	<p>REAL for slaeda</p> <p>DOUBLE PRECISION for dlaeda.</p> <p>Workspace array, dimension (n).</p>

Output Parameters

<i>z</i>	REAL for slaeda
----------	-----------------

DOUBLE PRECISION for dlaeda.

Array, dimension (n). Contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?laein

Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.

Syntax

call slaein(*rightv*, *noinit*, *n*, *h*, *ldh*, *wr*, *wi*, *vr*, *vi*, *b*, *ldb*, *work*, *eps3*, *smlnum*, *bignum*, *info*)

call dlaein(*rightv*, *noinit*, *n*, *h*, *ldh*, *wr*, *wi*, *vr*, *vi*, *b*, *ldb*, *work*, *eps3*, *smlnum*, *bignum*, *info*)

call claein(*rightv*, *noinit*, *n*, *h*, *ldh*, *w*, *v*, *b*, *ldb*, *rwork*, *eps3*, *smlnum*, *info*)

call zlaein(*rightv*, *noinit*, *n*, *h*, *ldh*, *w*, *v*, *b*, *ldb*, *rwork*, *eps3*, *smlnum*, *info*)

Include Files

- mkl.fi

Description

The routine ?laein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (*wr*,*wi*) of a real upper Hessenberg matrix *H* (for real flavors slaein/dlaein) or to the eigenvalue *w* of a complex upper Hessenberg matrix *H* (for complex flavors claein/zlaein).

Input Parameters

rightv

LOGICAL.

If *rightv* = .TRUE., compute right eigenvector;

if *rightv* = .FALSE., compute left eigenvector.

noinit

LOGICAL.

If *noinit* = .TRUE., no initial vector is supplied in (*vr*,*vi*) or in *v* (for complex flavors);

if *noinit* = .FALSE., initial vector is supplied in (*vr*,*vi*) or in *v* (for complex flavors).

n

INTEGER. The order of the matrix *H* ($n \geq 0$).

h

REAL for slaein

DOUBLE PRECISION for dlaein

COMPLEX for claein

	DOUBLE COMPLEX for <code>zlaein</code> .
	Array $h(ldh, *)$.
	The second dimension of h must be at least $\max(1, n)$. Contains the upper Hessenberg matrix H .
ldh	INTEGER. The leading dimension of the array h ; $ldh \geq \max(1, n)$.
wr, wi	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code> .
	The real and imaginary parts of the eigenvalue of H whose corresponding right or left eigenvector is to be computed (for real flavors of the routine).
w	COMPLEX for <code>claein</code> DOUBLE COMPLEX for <code>zlaein</code> .
	The eigenvalue of H whose corresponding right or left eigenvector is to be computed (for complex flavors of the routine).
vr, vi	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code> .
	Arrays, dimension (n) each. Used for real flavors only. On entry, if <code>noinit</code> = <code>.FALSE.</code> and $wi = 0.0$, vr must contain a real starting vector for inverse iteration using the real eigenvalue wr ; if <code>noinit</code> = <code>.FALSE.</code> and $wi \neq 0.0$, vr and vi must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (wr, wi) ; otherwise vr and vi need not be set.
v	COMPLEX for <code>claein</code> DOUBLE COMPLEX for <code>zlaein</code> .
	Array, dimension (n) . Used for complex flavors only. On entry, if <code>noinit</code> = <code>.FALSE.</code> , v must contain a starting vector for inverse iteration; otherwise v need not be set.
b	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code> COMPLEX for <code>claein</code> DOUBLE COMPLEX for <code>zlaein</code> .
	Workspace array $b(l db, *)$. The second dimension of b must be at least $\max(1, n)$.
$l db$	INTEGER. The leading dimension of the array b ; $l db \geq n+1$ for real flavors; $l db \geq \max(1, n)$ for complex flavors.
$work$	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code> .
	Workspace array, dimension (n) .

Used for real flavors only.

rwork

REAL for claein

DOUBLE PRECISION for zlaein.

Workspace array, dimension (*n*).

Used for complex flavors only.

eps3, smlnum

REAL for slaein/claein

DOUBLE PRECISION for dlaein/zlaein.

eps3 is a small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots.

smlnum is a machine-dependent value close to underflow threshold. A suggested value for *smlnum* is `slamch('s') * (n/slamch('p'))` for slaein/claein or `dlamch('s') * (n/dlamch('p'))` for dlaein/zlaein. See [lamch](#).

bignum

REAL for slaein

DOUBLE PRECISION for dlaein.

bignum is a machine-dependent value close to overflow threshold. Used for real flavors only. A suggested value for *bignum* is `1 / slamch('s')` for slaein/claein or `1 / dlamch('s')` for dlaein/zlaein.

Output Parameters

vr, vi

On exit, if *wi* = 0.0 (real eigenvalue), *vr* contains the computed real eigenvector; if *wi* ≠ 0.0 (complex eigenvalue), *vr* and *vi* contain the real and imaginary parts of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (*x,y*) is taken to be $|x| + |y|$.

vi is not referenced if *wi* = 0.0.

v

On exit, *v* contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (*x,y*) is taken to be $|x| + |y|$.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = 1, inverse iteration did not converge. For real flavors, *vr* is set to the last iterate, and so is *vi*, if *wi* ≠ 0.0. For complex flavors, *v* is set to the last iterate.

?laev2

Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.

Syntax

```
call slaev2( a, b, c, rt1, rt2, cs1, sn1 )
```

```
call dlaev2( a, b, c, rt1, rt2, cs1, sn1 )
call claev2( a, b, c, rt1, rt2, cs1, sn1 )
call zlaev2( a, b, c, rt1, rt2, cs1, sn1 )
```

Include Files

- mkl.fi

Description

The routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix} \text{ (for slaev2/dlaev2) or Hermitian matrix } \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix}$$

(for claev2/zlaev2).

On return, *rt1* is the eigenvalue of larger absolute value, *rt2* of smaller absolute value, and (*cs1*, *sn1*) is the unit right eigenvector for *rt1*, giving the decomposition

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for slaev2/dlaev2),

or

$$\begin{bmatrix} cs1 & \text{conjg}(sn1) \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -\text{conjg}(sn1) \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for claev2/zlaev2).

Input Parameters

a, *b*, *c* REAL for slaev2
 DOUBLE PRECISION for dlaev2
 COMPLEX for claev2
 DOUBLE COMPLEX for zlaev2.
 Elements of the input matrix.

Output Parameters

rt1, *rt2* REAL for slaev2/claev2
 DOUBLE PRECISION for dlaev2/zlaev2.
 Eigenvalues of larger and smaller absolute value, respectively.

cs1 REAL for slaev2/claev2
DOUBLE PRECISION for dlaev2/zlaev2.

sn1 REAL for slaev2
DOUBLE PRECISION for dlaev2
COMPLEX for claev2
DOUBLE COMPLEX for zlaev2.

The vector (*cs1*, *sn1*) is the unit right eigenvector for *rt1*.

Application Notes

rt1 is accurate to a few ulps barring over/underflow. *rt2* may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute *rt2* accurately in all cases. *cs1* and *sn1* are accurate to a few ulps barring over/underflow. Overflow is possible only if *rt1* is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds *underflow_threshold* / macheps.

?laexc

Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

```
call slaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
call dlaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
```

Include Files

- mkl.fi

Description

The routine swaps adjacent diagonal blocks T_{11} and T_{22} of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

wantq LOGICAL.
If *wantq* = .TRUE., accumulate the transformation in the matrix Q ;
If *wantq* = .FALSE., do not accumulate the transformation.

n INTEGER. The order of the matrix T ($n \geq 0$).

t, q REAL for slaexc
DOUBLE PRECISION for dlaexc
Arrays:

$t(ldt,*)$ contains on entry the upper quasi-triangular matrix T , in Schur canonical form.

The second dimension of t must be at least $\max(1, n)$.

$q(ldq,*)$ contains on entry, if $wantq = .TRUE.$, the orthogonal matrix Q . If $wantq = .FALSE.$, q is not referenced. The second dimension of q must be at least $\max(1, n)$.

ldt INTEGER. The leading dimension of t ; at least $\max(1, n)$.

ldq INTEGER. The leading dimension of q ;
If $wantq = .FALSE.$, then $ldq \geq 1$.
If $wantq = .TRUE.$, then $ldq \geq \max(1, n)$.

j1 INTEGER. The index of the first row of the first block T_{11} .

n1 INTEGER. The order of the first block T_{11}
($n1 = 0, 1$, or 2).

n2 INTEGER. The order of the second block T_{22}
($n2 = 0, 1$, or 2).

work REAL for slaexc;
DOUBLE PRECISION for dlaexc.
Workspace array, DIMENSION (n).

Output Parameters

t On exit, the updated matrix T , again in Schur canonical form.

q On exit, if $wantq = .TRUE.$, the updated matrix Q .

info INTEGER.
If $info = 0$, the execution is successful.
If $info = 1$, the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

?lag2

Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.

Syntax

```
call slag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
```

```
call dlag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
```

Include Files

- mkl.fi

Description

The routine computes the eigenvalues of a 2 x 2 generalized eigenvalue problem $A - w*B$, with scaling as necessary to avoid over-/underflow. The scaling factor, s , results in a modified eigenvalue equation

$$s*A - w*B,$$

where s is a non-negative scaling factor chosen so that w , $w*B$, and $s*A$ do not overflow and, if possible, do not underflow, either.

Input Parameters

a, b	<p>REAL for <code>slag2</code></p> <p>DOUBLE PRECISION for <code>dlag2</code></p> <p>Arrays:</p> <p>$a(lda, 2)$ contains, on entry, the 2 x 2 matrix A. It is assumed that its 1-norm is less than $1/safmin$. Entries less than $\sqrt{safmin} * \text{norm}(A)$ are subject to being treated as zero.</p> <p>$b(lb, 2)$ contains, on entry, the 2 x 2 upper triangular matrix B. It is assumed that the one-norm of B is less than $1/safmin$. The diagonals should be at least \sqrt{safmin} times the largest element of B (in absolute value); if a diagonal is smaller than that, then $\pm \sqrt{safmin}$ will be used instead of that diagonal.</p>
lda	INTEGER. The leading dimension of a ; $lda \geq 2$.
ldb	INTEGER. The leading dimension of b ; $ldb \geq 2$.
$safmin$	<p>REAL for <code>slag2</code>;</p> <p>DOUBLE PRECISION for <code>dlag2</code>.</p> <p>The smallest positive number such that $1/safmin$ does not overflow. (This should always be <code>?lamch('S')</code> - it is an argument in order to avoid having to call <code>?lamch</code> frequently.)</p>

Output Parameters

$scale1$	<p>REAL for <code>slag2</code>;</p> <p>DOUBLE PRECISION for <code>dlag2</code>.</p> <p>A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are $(wr1 \pm wii)/scale1$ (which may lie outside the exponent range of the machine), $scale1=scale2$, and $scale1$ will always be positive.</p> <p>If the eigenvalues are real, then the first (real) eigenvalue is $wr1/scale1$, but this may overflow or underflow, and in fact, $scale1$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.</p>
$scale2$	<p>REAL for <code>slag2</code>;</p> <p>DOUBLE PRECISION for <code>dlag2</code>.</p>

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then $scale2=scale1$. If the eigenvalues are real, then the second (real) eigenvalue is $wr2/scale2$, but this may overflow or underflow, and in fact, $scale2$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

*wr1*REAL for *slag2*;DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then *wr1* is $scale1$ times the eigenvalue closest to the (2,2) element of $A*inv(B)$.

If the eigenvalue is complex, then $wr1=wr2$ is $scale1$ times the real part of the eigenvalues.

*wr2*REAL for *slag2*;DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then *wr2* is $scale2$ times the other eigenvalue. If the eigenvalue is complex, then $wr1=wr2$ is $scale1$ times the real part of the eigenvalues.

*wi*REAL for *slag2*;DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then *wi* is zero. If the eigenvalue is complex, then *wi* is $scale1$ times the imaginary part of the eigenvalues. *wi* will always be non-negative.

?lags2

Computes 2-by-2 orthogonal matrices U, V, and Q, and applies them to matrices A and B such that the rows of the transformed A and B are parallel.

Syntax

```
call slags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
```

```
call dlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
```

```
call clags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
```

```
call zlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq)
```

Include Files

- mkl.fi

Description

For real flavors, the routine computes 2-by-2 orthogonal matrices *U*, *V* and *Q*, such that if *upper* = .TRUE., then

$$\begin{pmatrix} a1 & a2 \\ a3 & a4 \end{pmatrix} \begin{pmatrix} b1 & b2 \\ b3 & b4 \end{pmatrix} = \begin{pmatrix} c1 & c2 \\ c3 & c4 \end{pmatrix} \begin{pmatrix} s1 & s2 \\ s3 & s4 \end{pmatrix}$$

and

$$V^T * B * Q = V^T * \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if `upper = .FALSE.`, then

$$U^T * A * Q = U^T * \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu & csu \end{bmatrix}, V = \begin{bmatrix} csv & snv \\ -snv & csv \end{bmatrix}, Q = \begin{bmatrix} csq & snq \\ -snq & csq \end{bmatrix}$$

Here Z^T denotes the transpose of Z .

For complex flavors, the routine computes 2-by-2 unitary matrices U , V and Q , such that if `upper = .TRUE.`, then

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

and

$$V^H * B * Q = V^H * \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if `upper = .FALSE.`, then

$$U^H * A * Q = U^H * \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$V^H * B * Q = V^H * \begin{bmatrix} B_1 & 0 \\ B_2 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu^H & csu \end{bmatrix}, V = \begin{bmatrix} csv & snv \\ -snv^H & csv \end{bmatrix}, Q = \begin{bmatrix} csq & snq \\ -snq^H & csq \end{bmatrix}$$

Input Parameters

<i>upper</i>	LOGICAL. If <i>upper</i> = .TRUE., the input matrices A and B are upper triangular; If <i>upper</i> = .FALSE., the input matrices A and B are lower triangular.
<i>a1, a3</i>	REAL for <i>slags2</i> and <i>clags2</i> DOUBLE PRECISION for <i>dlags2</i> and <i>zlags2</i>
<i>a2</i>	REAL for <i>slags2</i> DOUBLE PRECISION for <i>dlags2</i> COMPLEX for <i>clags2</i> COMPLEX*16 for <i>zlags2</i> On entry, <i>a1</i> , <i>a2</i> and <i>a3</i> are elements of the input 2-by-2 upper (lower) triangular matrix A .
<i>b1, b3</i>	REAL for <i>slags2</i> and <i>clags2</i> DOUBLE PRECISION for <i>dlags2</i> and <i>zlags2</i>
<i>b2</i>	REAL for <i>slags2</i> DOUBLE PRECISION for <i>dlags2</i> COMPLEX for <i>clags2</i> COMPLEX*16 for <i>zlags2</i> On entry, <i>b1</i> , <i>b2</i> and <i>b3</i> are elements of the input 2-by-2 upper (lower) triangular matrix B .

Output Parameters

<i>csu</i>	<p>REAL for slags2 and clags2</p> <p>DOUBLE PRECISION for dlags2 and zlags2</p> <p>Element of the desired orthogonal matrix <i>U</i>.</p>
<i>snu</i>	<p>REAL for slags2</p> <p>DOUBLE PRECISION for dlags2</p> <p>Element of the desired orthogonal matrix <i>U</i>.</p> <p>COMPLEX for clags2</p> <p>COMPLEX*16 for zlags2</p>
<i>csv</i>	<p>REAL for slags2 and clags2</p> <p>DOUBLE PRECISION for dlags2 and zlags2</p> <p>Element of the desired orthogonal matrix <i>V</i>.</p>
<i>snv</i>	<p>REAL for slags2</p> <p>DOUBLE PRECISION for dlags2</p> <p>COMPLEX for clags2</p> <p>COMPLEX*16 for zlags2</p> <p>Element of the desired orthogonal matrix <i>V</i>.</p>
<i>csq</i>	<p>REAL for slags2 and clags2</p> <p>DOUBLE PRECISION for dlags2 and zlags2</p> <p>Element of the desired orthogonal matrix <i>Q</i>.</p>
<i>snq</i>	<p>REAL for slags2</p> <p>DOUBLE PRECISION for dlags2</p> <p>Element of the desired orthogonal matrix <i>Q</i>.</p> <p>COMPLEX for clags2</p> <p>COMPLEX*16 for zlags2</p>

?lagtf

*Computes an LU factorization of a matrix $T - \lambda * I$, where T is a general tridiagonal matrix, and λ is a scalar, using partial pivoting with row interchanges.*

Syntax

```
call slagtf( n, a, lambda, b, c, tol, d, in, info )
call dlagtf( n, a, lambda, b, c, tol, d, in, info )
```

Include Files

- mkl.fi

Description

The routine factorizes the matrix $(T - \lambda I)$, where T is an n -by- n tridiagonal matrix and λ is a scalar, as

$$T - \lambda I = P^* L^* U,$$

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column. The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling. The parameter λ is included in the routine so that `?lagtf` may be used, in conjunction with `?lagts`, to obtain eigenvectors of T by inverse iteration.

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
a, b, c	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> Arrays, dimension $a(n)$, $b(n-1)$, $c(n-1)$: On entry, $a(*)$ must contain the diagonal elements of the matrix T . On entry, $b(*)$ must contain the $(n-1)$ super-diagonal elements of T . On entry, $c(*)$ must contain the $(n-1)$ sub-diagonal elements of T .
tol	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. tol should normally be chosen as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then tol should be set to about 5×10^{-4} . If tol is supplied as less than ϵ , where ϵ is the relative machine precision, then the value ϵ is used in place of tol .

Output Parameters

a	On exit, a is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .
b	On exit, b is overwritten by the $n-1$ super-diagonal elements of the matrix U of the factorization of T .
c	On exit, c is overwritten by the $n-1$ sub-diagonal elements of the matrix L of the factorization of T .
d	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> Array, dimension $(n-2)$. On exit, d is overwritten by the $n-2$ second super-diagonal elements of the matrix U of the factorization of T .
in	INTEGER.

Array, dimension (n).

On exit, in contains details of the permutation matrix p . If an interchange occurred at the k -th step of the elimination, then $in(k) = 1$, otherwise $in(k) = 0$. The element $in(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}((T - \text{lambda} * I)(j)) * \text{tol},$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the j -th row of the matrix A .

If no such j exists then $in(n)$ is returned as zero. If $in(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \text{lambda} * I)$ is singular or nearly singular.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -k$, the k -th parameter had an illegal value.

?slagtm

Performs a matrix-matrix product of the form $C = \alpha * A * B + \beta * C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.

Syntax

```
call slagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call dlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call clagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call zlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
```

Include Files

- mkl.fi

Description

The routine performs a matrix-vector product of the form:

$$B := \alpha * A * X + \beta * B$$

where A is a tridiagonal matrix of order n , B and X are n -by- $nrhs$ matrices, and α and β are real scalars, each of which may be 0., 1., or -1.

Input Parameters

$trans$

CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If $trans = 'N'$, then $B := \alpha * A * X + \beta * B$ (no transpose);

If $trans = 'T'$, then $B := \alpha * A^T * X + \beta * B$ (transpose);

If $trans = 'C'$, then $B := \alpha * A^H * X + \beta * B$ (conjugate transpose)

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides, i.e., the number of columns in <i>X</i> and <i>B</i> ($nrhs \geq 0$).
<i>alpha, beta</i>	REAL for <i>slagtm</i> / <i>clagtm</i> DOUBLE PRECISION for <i>dlagtm</i> / <i>zlagtm</i> Specify the scalars <i>alpha</i> and <i>beta</i> respectively. <i>alpha</i> must be 0., 1., or -1.; otherwise, it is assumed to be 0. <i>beta</i> must be 0., 1., or -1.; otherwise, it is assumed to be 1.
<i>dl, d, du</i>	REAL for <i>slagtm</i> DOUBLE PRECISION for <i>dlagtm</i> COMPLEX for <i>clagtm</i> DOUBLE COMPLEX for <i>zlagtm</i> . Arrays: <i>dl</i> (<i>n</i> - 1), <i>d</i> (<i>n</i>), <i>du</i> (<i>n</i> - 1). The array <i>dl</i> contains the (<i>n</i> - 1) sub-diagonal elements of <i>T</i> . The array <i>d</i> contains the <i>n</i> diagonal elements of <i>T</i> . The array <i>du</i> contains the (<i>n</i> - 1) super-diagonal elements of <i>T</i> .
<i>x, b</i>	REAL for <i>slagtm</i> DOUBLE PRECISION for <i>dlagtm</i> COMPLEX for <i>clagtm</i> DOUBLE COMPLEX for <i>zlagtm</i> . Arrays: <i>x</i> (<i>ldx</i> ,*) contains the <i>n</i> -by- <i>nrhs</i> matrix <i>X</i> . The second dimension of <i>x</i> must be at least $\max(1, nrhs)$. <i>b</i> (<i>ldb</i> ,*) contains the <i>n</i> -by- <i>nrhs</i> matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldx</i>	INTEGER. The leading dimension of the array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the matrix expression $B := \alpha A * X + \beta A * B$
----------	--

?lagts

Solves the system of equations $(T - \lambda I) * x = y$ or $(T - \lambda I)^T * x = y$, where *T* is a general tridiagonal matrix and λ is a scalar, using the LU factorization computed by ?lagtf.

Syntax

call slagts(job, n, a, b, c, d, in, y, tol, info)

call dlagts(job, n, a, b, c, d, in, y, tol, info)

Include Files

- mkl.fi

Description

The routine may be used to solve for x one of the systems of equations:

$$(T - \lambda I)x = y \text{ or } (T - \lambda I)^T x = y,$$

where T is an n -by- n tridiagonal matrix, following the factorization of $(T - \lambda I)$ as

$$T - \lambda I = P^* L^* U,$$

computed by the routine [?lagtf](#).

The choice of equation to be solved is controlled by the argument *job*, and in each case there is an option to perturb zero or very small diagonal elements of U , this option being intended for use in applications such as inverse iteration.

Input Parameters

<i>job</i>	<p>INTEGER. Specifies the job to be performed by <code>?lagts</code> as follows:</p> <ul style="list-style-type: none"> = 1: The equations $(T - \lambda I)x = y$ are to be solved, but diagonal elements of U are not to be perturbed. = -1: The equations $(T - \lambda I)x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below. = 2: The equations $(T - \lambda I)^T x = y$ are to be solved, but diagonal elements of U are not to be perturbed. = -2: The equations $(T - \lambda I)^T x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below.
<i>n</i>	<p>INTEGER. The order of the matrix T ($n \geq 0$).</p>
<i>a, b, c, d</i>	<p>REAL for <code>slagts</code></p> <p>DOUBLE PRECISION for <code>dlagts</code></p> <p>Arrays, dimension $a(n)$, $b(n-1)$, $c(n-1)$, $d(n-2)$:</p> <p>On entry, $a(*)$ must contain the diagonal elements of U as returned from <code>?lagtf</code>.</p> <p>On entry, $b(*)$ must contain the first super-diagonal elements of U as returned from <code>?lagtf</code>.</p> <p>On entry, $c(*)$ must contain the sub-diagonal elements of L as returned from <code>?lagtf</code>.</p> <p>On entry, $d(*)$ must contain the second super-diagonal elements of U as returned from <code>?lagtf</code>.</p>
<i>in</i>	<p>INTEGER.</p> <p>Array, dimension (n).</p>

On entry, *in*(*) must contain details of the matrix *p* as returned from ?lagtf.

y

REAL for slagts

DOUBLE PRECISION for dlagts

Array, dimension (*n*). On entry, the right hand side vector *y*.

tol

REAL for slagtf

DOUBLE PRECISION for dlagtf.

On entry, with *job* < 0, *tol* should be the minimum perturbation to be made to very small diagonal elements of *U*. *tol* should normally be chosen as about *eps**norm(*U*), where *eps* is the relative machine precision, but if *tol* is supplied as non-positive, then it is reset to *eps**max(abs(u(*i*,*j*))). If *job* > 0 then *tol* is not referenced.

Output Parameters

y

On exit, *y* is overwritten by the solution vector *x*.

tol

On exit, *tol* is changed as described in *Input Parameters* section above, only if *tol* is non-positive on entry. Otherwise *tol* is unchanged.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value. If *info* = *i* > 0, overflow would occur when computing the *i*th element of the solution vector *x*. This can only occur when *job* is supplied as positive and either means that a diagonal element of *U* is very small, or that the elements of the right-hand side vector *y* are very large.

?lagv2

Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (*A*,*B*) where *B* is upper triangular.

Syntax

```
call slagv2( a, lda, b, ldb, alphas, alphai, beta, csl, snl, csr, snr )
```

```
call dlagv2( a, lda, b, ldb, alphas, alphai, beta, csl, snl, csr, snr )
```

Include Files

- mkl.fi

Description

The routine computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (*A*,*B*) where *B* is upper triangular. The routine computes orthogonal (rotation) matrices given by *csl*, *snl* and *csr*, *snr* such that:

- 1) if the pencil (*A*,*B*) has two real eigenvalues (include 0/0 or 1/0 types), then

$$\begin{bmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

2) if the pencil (A,B) has a pair of complex conjugate eigenvalues, then

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & 0 \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

where $b_{11} \geq b_{22} > 0$.

Input Parameters

a, b REAL for slagv2
 DOUBLE PRECISION for dlagv2

Arrays:
a(lda,2) contains the 2-by-2 matrix *A*;
b(ldb,2) contains the upper triangular 2-by-2 matrix *B*.

lda INTEGER. The leading dimension of the array *a*;
 $lda \geq 2$.

ldb INTEGER. The leading dimension of the array *b*;
 $ldb \geq 2$.

Output Parameters

a On exit, *a* is overwritten by the "A-part" of the generalized Schur form.

b On exit, *b* is overwritten by the "B-part" of the generalized Schur form.

alphar, alphai, beta REAL for slagv2
 DOUBLE PRECISION for dlagv2.
 Arrays, dimension (2) each.
 $(\text{alphar}(k) + i \cdot \text{alphai}(k)) / \text{beta}(k)$ are the eigenvalues of the pencil (A,B) , $k=1,2$ and $i = \text{sqrt}(-1)$.

Note that *beta(k)* may be zero.

csl, snl

REAL for *slagv2*

DOUBLE PRECISION for *dlagv2*

The cosine and sine of the left rotation matrix, respectively.

csr, snr

REAL for *slagv2*

DOUBLE PRECISION for *dlagv2*

The cosine and sine of the right rotation matrix, respectively.

?lahqr

Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.

Syntax

```
call slahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, info )
```

```
call dlahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, info )
```

```
call clahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
```

```
call zlahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info )
```

Include Files

- mkl.fi

Description

The routine is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*.

Input Parameters

wantt

LOGICAL.

If *wantt* = .TRUE., the full Schur form *T* is required;

If *wantt* = .FALSE., eigenvalues only are required.

wantz

LOGICAL.

If *wantz* = .TRUE., the matrix of Schur vectors *Z* is required;

If *wantz* = .FALSE., Schur vectors are not required.

n

INTEGER. The order of the matrix *H* ($n \geq 0$).

ilo, ihi

INTEGER.

It is assumed that *h* is already upper quasi-triangular in rows and columns *ihl+1:n*, and that $h(ilo, ilo-1) = 0$ (unless *ilo* = 1). The routine ?lahqr works primarily with the Hessenberg submatrix in rows and columns *ilo* to *ihi*, but applies transformations to all of *h* if *wantt* = .TRUE..

Constraints:

$1 \leq ilo \leq \max(1, ihi); ihi \leq n.$

h, z

REAL for slahqr

DOUBLE PRECISION for dlahqr

COMPLEX for clahqr

DOUBLE COMPLEX for zlahqr.

Arrays:

h(ldh,)* contains the upper Hessenberg matrix *h*.

The second dimension of *h* must be at least $\max(1, n)$.

z(ldz,)*

If *wantz* = .TRUE., then, on entry, *z* must contain the current matrix *z* of transformations accumulated by ?hseqr. The second dimension of *z* must be at least $\max(1, n)$

If *wantz* = .FALSE., then *z* is not referenced..

ldh

INTEGER. The leading dimension of *h*; at least $\max(1, n)$.

ldz

INTEGER. The leading dimension of *z*; at least $\max(1, n)$.

iloz, ihiz

INTEGER. Specify the rows of *z* to which transformations must be applied if *wantz* = .TRUE..

$1 \leq iloz \leq ilo; ihi \leq ihiz \leq n.$

Output Parameters

h

On exit, if *info*= 0 and *wantt* = .TRUE., then,

- for slahqr/dlahqr, *h* is upper quasi-triangular in rows and columns *ilo:ihi* with any 2-by-2 diagonal blocks in standard form.
- for clahqr/zlahqr, *h* is upper triangular in rows and columns *ilo:ihi*.

If *info*= 0 and *wantt* = .FALSE., the contents of *h* are unspecified on exit. If *info* is positive, see description of *info* for the output state of *h*.

wr, wi

REAL for slahqr

DOUBLE PRECISION for dlahqr

Arrays, DIMENSION at least $\max(1, n)$ each. Used with real flavors only. The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0.

If *wantt* = .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *wr*(*i*) = *h*(*i, i*), and, if *h*(*i:i+1, i:i+1*) is a 2-by-2 diagonal block, *wi*(*i*) = sqrt(*h*(*i*+1, *i*)**h*(*i, i+1*)) and *wi*(*i*+1) = -*wi*(*i*).

<i>w</i>	<p>COMPLEX for <code>clahqr</code></p> <p>DOUBLE COMPLEX for <code>zlahqr</code>.</p> <p>Array, DIMENSION at least $\max(1, n)$. Used with complex flavors only. The computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>w</i>.</p> <p>If <i>wantt</i> = <code>.TRUE.</code>, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i>, with $w(i) = h(i, i)$.</p>
<i>z</i>	<p>If <i>wantz</i> = <code>.TRUE.</code>, then, on exit <i>z</i> has been updated; transformations are applied only to the submatrix <i>z(ilo:ihiz, ilo:ihi)</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>With <i>info</i> > 0,</p> <ul style="list-style-type: none"> • if <i>info</i> = <i>i</i>, <code>?lahqr</code> failed to compute all the eigenvalues <i>ilo</i> to <i>ihi</i> in a total of 30 iterations per eigenvalue; elements <i>i+1:ihiz</i> of <i>wr</i> and <i>wi</i> (for <code>slahqr/dlahqr</code>) or <i>w</i> (for <code>clahqr/zlahqr</code>) contain those eigenvalues which have been successfully computed. • if <i>wantt</i> is <code>.FALSE.</code>, then on exit the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns <i>ilo</i> through <i>info</i> of the final output value of <i>h</i>. • if <i>wantt</i> is <code>.TRUE.</code>, then on exit $(\text{initial value of } h) * u = u * (\text{final value of } h), \quad (*)$ where <i>u</i> is an orthogonal matrix. The final value of <i>h</i> is upper Hessenberg and triangular in rows and columns <i>info+1</i> through <i>ihi</i>. • if <i>wantz</i> is <code>.TRUE.</code>, then on exit $(\text{final value of } z) = (\text{initial value of } z) * u,$ where <i>u</i> is an orthogonal matrix in $(*)$ regardless of the value of <i>wantt</i>.

?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k-th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A.

Syntax

```
call slahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Include Files

- `mkl.fi`

Description

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation $Q^T A Q$ for real flavors, or $Q^H A Q$ for complex flavors. The routine returns the matrices V and T which determine Q as a block reflector $I - V^* T^* V^T$ (for real flavors) or $I - V^* T^* V^H$ (for complex flavors), and also the matrix $Y = A^* V^* T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v v^H \text{ for complex flavors, or}$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an obsolete auxiliary routine. Please use the new routine `?lahr2` instead.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	INTEGER. The number of columns to be reduced.
a	REAL for <code>slahrd</code> DOUBLE PRECISION for <code>dlahrd</code> COMPLEX for <code>clahrd</code> DOUBLE COMPLEX for <code>zlahrd</code> . Array $a(lda, n-k+1)$ contains the n -by- $(n-k+1)$ general matrix A to be reduced.
lda	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
ldt	INTEGER. The leading dimension of the output array t ; must be at least $\max(1, nb)$.
ldy	INTEGER. The leading dimension of the output array y ; must be at least $\max(1, n)$.

Output Parameters

a	On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k -th subdiagonal, with the array τ , represent the matrix Q as a product of elementary reflectors. The other columns of a are unchanged. See <i>Application Notes</i> below.
τ	REAL for <code>slahrd</code> DOUBLE PRECISION for <code>dlahrd</code> COMPLEX for <code>clahrd</code> DOUBLE COMPLEX for <code>zlahrd</code> .

Array, DIMENSION (nb).

Contains scalar factors of the elementary reflectors.

t, y

REAL for `slahrd`

DOUBLE PRECISION for `dlahrd`

COMPLEX for `clahrd`

DOUBLE COMPLEX for `zlahrd`.

Arrays, dimension $t(ldt, nb)$, $y(ldy, nb)$.

The array t contains upper triangular matrix T .

The array y contains the n -by- nb matrix Y .

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and τ is stored in $\tau(i)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form:

$A := (I - V^* T^* V^T) * (A - Y^* V^T)$ for real flavors, or

$A := (I - V^* T^* V^H) * (A - Y^* V^H)$ for complex flavors.

The contents of A on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and τ is stored in $\tau(i)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form:

$A := (I - V^* T^* V^T) * (A - Y^* V^T)$ for real flavors, or

$A := (I - V^* T^* V^H) * (A - Y^* V^H)$ for complex flavors.

The contents of A on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & a & a & a & a \\ a & a & a & a & a \\ a & a & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?laic1

Applies one step of incremental condition estimation.

Syntax

```
call slaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call dlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call claic1( job, j, x, sest, w, gamma, sestpr, s, c )
call zlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
```

Include Files

- mkl.fi

Description

The routine ?laic1 applies one step of incremental condition estimation in its simplest version.

Let x , $\|x\|_2 = 1$ (where $\|a\|_2$ denotes the 2-norm of a), be an approximate singular vector of an j -by- j lower triangular matrix L , such that

$$\|Lx\|_2 = \text{sest}$$

Then ?laic1 computes sestpr , s , c such that the vector

$$x_{\text{hat}} = \begin{bmatrix} s^*x \\ c \end{bmatrix}$$

is an approximate singular vector of

$$L_{\text{hat}} = \begin{bmatrix} L & 0 \\ w^x & \text{gamma} \end{bmatrix} \text{ (for complex flavors), or}$$

$$L_{\text{hat}} = \begin{bmatrix} L & 0 \\ w^T & \text{gamma} \end{bmatrix} \text{ (for real flavors), in the sense that}$$

$$\|L_{\text{hat}}x_{\text{hat}}\|_2 = \text{sestpr}.$$

Depending on job , an estimate for the largest or smallest singular value is computed.

For real flavors, $[sc]^T$ and sestpr^2 is an eigenpair of the system

$$\text{diag}(\text{sest}^* \text{sest}, 0) + [\text{alpha} \text{ gamma}] * \begin{bmatrix} \text{alpha} \\ \text{gamma} \end{bmatrix}$$

where $\text{alpha} = x^T w$.

For complex flavors, $[sc]^H$ and sestpr^2 is an eigenpair of the system

$$\text{diag}(sest*sest, 0) + [\alpha \ \gamma] * \begin{bmatrix} \text{conjg}(\alpha) \\ \text{conjg}(\gamma) \end{bmatrix}$$

where $\alpha = x^H w$.

Input Parameters

<i>job</i>	INTEGER. If <i>job</i> =1, an estimate for the largest singular value is computed; If <i>job</i> =2, an estimate for the smallest singular value is computed;
<i>j</i>	INTEGER. Length of <i>x</i> and <i>w</i> .
<i>x, w</i>	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 DOUBLE COMPLEX for zlaic1. Arrays, dimension (<i>j</i>) each. Contain vectors <i>x</i> and <i>w</i> , respectively.
<i>sest</i>	REAL for slaic1/claic1; DOUBLE PRECISION for dlaic1/zlaic1. Estimated singular value of <i>j</i> -by- <i>j</i> matrix <i>L</i> .
<i>gamma</i>	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 DOUBLE COMPLEX for zlaic1. The diagonal element <i>gamma</i> .

Output Parameters

<i>sestpr</i>	REAL for slaic1/claic1; DOUBLE PRECISION for dlaic1/zlaic1. Estimated singular value of (<i>j</i> +1)-by-(<i>j</i> +1) matrix <i>Lhat</i> .
<i>s, c</i>	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 DOUBLE COMPLEX for zlaic1. Sine and cosine needed in forming <i>xhat</i> .

?lakf2

Forms a matrix containing Kronecker products between the given matrices.

Syntax

```
call slakf2( m, n, a, lda, b, d, e, z, ldz )
call dlakf2( m, n, a, lda, b, d, e, z, ldz )
call clakf2( m, n, a, lda, b, d, e, z, ldz )
call zlakf2( m, n, a, lda, b, d, e, z, ldz )
```

Include Files

- mkl.fi

Description

The routine ?lakf2 forms the $2*m*n$ by $2*m*n$ matrix Z .

$$Z = \begin{bmatrix} \text{kron}(In, A) & -\text{kron}(B^T, Im) \\ \text{kron}(In, D) & -\text{kron}(E^T, Im) \end{bmatrix},$$

where In is the identity matrix of size n and X^T is the transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

Input Parameters

m	INTEGER. Size of matrix, $m \geq 1$
n	INTEGER. Size of matrix, $n \geq 1$
a	REAL for slakf2, DOUBLE PRECISION for dlakf2, COMPLEX for clakf2, DOUBLE COMPLEX for zlakf2, Array, size lda -by- n . The matrix A in the output matrix Z .
lda	INTEGER. The leading dimension of a , b , d , and e . $lda \geq m+n$.
b	REAL for slakf2, DOUBLE PRECISION for dlakf2, COMPLEX for clakf2, DOUBLE COMPLEX for zlakf2, Array, size lda by n . Matrix used in forming the output matrix Z .
d	REAL for slakf2, DOUBLE PRECISION for dlakf2, COMPLEX for clakf2,

DOUBLE COMPLEX for `zlakf2`,
 Array, size *lda* by *m*. Matrix used in forming the output matrix *Z*.

e REAL for `slakf2`,
 DOUBLE PRECISION for `dlakf2`,
 COMPLEX for `clakf2`,
 DOUBLE COMPLEX for `zlakf2`,
 Array, size *lda* by *n*. Matrix used in forming the output matrix *Z*.

ldz INTEGER. The leading dimension of *Z*. $ldz \geq 2 * m * n$.

Output Parameters

z REAL for `slakf2`,
 DOUBLE PRECISION for `dlakf2`,
 COMPLEX for `clakf2`,
 DOUBLE COMPLEX for `zlakf2`,
 Array, size *ldz*-by- $2 * m * n$. The resultant Kronecker $m * n * 2$ -by- $m * n * 2$ matrix.

?laln2

Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.

Syntax

```
call slaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx, scale,
xnorm, info )
call dlaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx, scale,
xnorm, info )
```

Include Files

- `mk1.fi`

Description

The routine solves a system of the form

$$(ca * A - w * D) * X = s * B, \text{ or } (ca * A^T - w * D) * X = s * B$$

with possible scaling (*s*) and perturbation of *A*.

A is an *na*-by-*na* real matrix, *ca* is a real scalar, *D* is an *na*-by-*na* real diagonal matrix, *w* is a real or complex value, and *X* and *B* are *na*-by-1 matrices: real if *w* is real, complex if *w* is complex. The parameter *na* may be 1 or 2.

If *w* is complex, *X* and *B* are represented as *na*-by-2 matrices, the first column of each being the real part and the second being the imaginary part.

The routine computes the scaling factor *s* (≤ 1) so chosen that *X* can be computed without overflow. *X* is further scaled if necessary to assure that $\text{norm}(ca * A - w * D) * \text{norm}(X)$ is less than overflow.

If both singular values of $(ca*A - w*D)$ are less than $smin$, $smin*I$ (where I stands for identity) will be used instead of $(ca*A - w*D)$. If only one singular value is less than $smin$, one element of $(ca*A - w*D)$ will be perturbed enough to make the smallest singular value roughly $smin$.

If both singular values are at least $smin$, $(ca*A - w*D)$ will not be perturbed. In any case, the perturbation will be at most some small multiple of $\max(smin, ulp*norm(ca*A - w*D))$.

The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

NOTE

All input quantities are assumed to be smaller than overflow by a reasonable factor (see *bignum*).

Input Parameters

<i>trans</i>	<p>LOGICAL.</p> <p>If <i>trans</i> = .TRUE., A- transpose will be used.</p> <p>If <i>trans</i> = .FALSE., A will be used (not transposed.)</p>
<i>na</i>	<p>INTEGER. The size of the matrix A, possible values 1 or 2.</p>
<i>nw</i>	<p>INTEGER. This parameter must be 1 if <i>w</i> is real, and 2 if <i>w</i> is complex. Possible values 1 or 2.</p>
<i>smin</i>	<p>REAL for slaln2</p> <p>DOUBLE PRECISION for dlaln2.</p> <p>The desired lower bound on the singular values of A.</p> <p>This should be a safe distance away from underflow or overflow, for example, between (<i>underflow/machine_precision</i>) and (<i>machine_precision * overflow</i>). (See <i>bignum</i> and <i>ulp</i>).</p>
<i>ca</i>	<p>REAL for slaln2</p> <p>DOUBLE PRECISION for dlaln2.</p> <p>The coefficient by which A is multiplied.</p>
<i>a</i>	<p>REAL for slaln2</p> <p>DOUBLE PRECISION for dlaln2.</p> <p>Array, DIMENSION (<i>lda,na</i>).</p> <p>The <i>na</i>-by-<i>na</i> matrix A.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of <i>a</i>. Must be at least <i>na</i>.</p>
<i>d1, d2</i>	<p>REAL for slaln2</p> <p>DOUBLE PRECISION for dlaln2.</p> <p>The (1,1) and (2,2) elements in the diagonal matrix D, respectively. <i>d2</i> is not used if <i>nw</i> = 1.</p>
<i>b</i>	<p>REAL for slaln2</p> <p>DOUBLE PRECISION for dlaln2.</p>

Array, DIMENSION (ldb, nw). The na -by- nw matrix B (right-hand side). If $nw = 2$ (w is complex), column 1 contains the real part of B and column 2 contains the imaginary part.

ldb INTEGER. The leading dimension of b . Must be at least na .

wr, wi REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.

The real and imaginary part of the scalar w , respectively.
 wi is not used if $nw = 1$.

ldx INTEGER. The leading dimension of the output array x . Must be at least na .

Output Parameters

x REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.

Array, DIMENSION (ldx, nw). The na -by- nw matrix X (unknowns), as computed by the routine. If $nw = 2$ (w is complex), on exit, column 1 will contain the real part of X and column 2 will contain the imaginary part.

scale REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.

The scale factor that B must be multiplied by to insure that overflow does not occur when computing X . Thus $(ca*A - w*D) X$ will be $scale*B$, not B (ignoring perturbations of A .) It will be at most 1.

xnorm REAL for `slaln2`
DOUBLE PRECISION for `dlaln2`.

The infinity-norm of X , when X is regarded as an na -by- nw real matrix.

info INTEGER.

An error flag. It will be zero if no error occurs, a negative number if an argument is in error, or a positive number if $(ca*A - w*D)$ had to be perturbed. The possible values are:

If $info = 0$: no error occurred, and $(ca*A - w*D)$ did not have to be perturbed.

If $info = 1$: $(ca*A - w*D)$ had to be perturbed to make its smallest (or only) singular value greater than $smin$.

NOTE

For higher speed, this routine does not check the inputs for errors.

slals0

Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd.

Syntax

```
call slals0( icalmpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call dlals0( icalmpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )

call clals0( icalmpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )

call zlals0( icalmpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
```

Include Files

Description

The routine applies back the multiplying factors of either the left or right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix *B* in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is *givptr*; the pairs of columns/rows they were applied to are stored in *givcol*; and the *c*- and *s*-values of these rotations are stored in *givnum*.

(2L) Permutation. The $(nl+1)$ -st row of *B* is to be moved to the first row, and for $j=2:n$, *perm*(*j*)-th row of *B* is to be moved to the *j*-th row.

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If *sqre* = 1, one extra Givens rotation to generate the right null space.

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Input Parameters

<i>icalmpq</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: If <i>icalmpq</i> = 0: Left singular vector matrix. If <i>icalmpq</i> = 1: Right singular vector matrix.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block.

	$nr \geq 1$.
<i>sqre</i>	<p>INTEGER.</p> <p>If <i>sqre</i> = 0: the lower block is an <i>nr</i>-by-<i>nr</i> square matrix.</p> <p>If <i>sqre</i> = 1: the lower block is an <i>nr</i>-by-(<i>nr</i>+1) rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.</p>
<i>nrhs</i>	<p>INTEGER. The number of columns of <i>B</i> and <i>bx</i>.</p> <p>Must be at least 1.</p>
<i>b</i>	<p>REAL for slals0</p> <p>DOUBLE PRECISION for dlals0</p> <p>COMPLEX for clals0</p> <p>DOUBLE COMPLEX for zlals0.</p> <p>Array, DIMENSION (<i>ldb</i>, <i>nrhs</i>).</p> <p>Contains the right hand sides of the least squares problem in rows 1 through <i>m</i>.</p>
<i>ldb</i>	<p>INTEGER. The leading dimension of <i>b</i>.</p> <p>Must be at least $\max(1, \max(m, n))$.</p>
<i>bx</i>	<p>REAL for slals0</p> <p>DOUBLE PRECISION for dlals0</p> <p>COMPLEX for clals0</p> <p>DOUBLE COMPLEX for zlals0.</p> <p>Workspace array, DIMENSION (<i>ldbx</i>, <i>nrhs</i>).</p>
<i>ldbx</i>	INTEGER. The leading dimension of <i>bx</i> .
<i>perm</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>).</p> <p>The permutations (from deflation and sorting) applied to the two blocks.</p>
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.
<i>ldgcol</i>	INTEGER. The leading dimension of <i>givcol</i> , must be at least <i>n</i> .
<i>givnum</i>	<p>REAL for slals0/clals0</p> <p>DOUBLE PRECISION for dlals0/zlals0</p> <p>Array, DIMENSION (<i>ldgnum</i>, 2). Each number indicates the <i>c</i> or <i>s</i> value used in the corresponding Givens rotation.</p>

<i>ldgnum</i>	INTEGER. The leading dimension of arrays <i>difr</i> , <i>poles</i> and <i>givnum</i> , must be at least <i>k</i> .
<i>poles</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). On entry, <i>poles</i> (1: <i>k</i> , 1) contains the new singular values obtained from solving the secular equation, and <i>poles</i> (1: <i>k</i> , 2) is an array containing the poles in the secular equation.
<i>difl</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>k</i>). On entry, <i>difl</i> (<i>i</i>) is the distance between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> -th (undeflated) old singular value.
<i>difr</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). On entry, <i>difr</i> (<i>i</i> , 1) contains the distances between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> +1-th (undeflated) old singular value. And <i>difr</i> (<i>i</i> , 2) is the normalizing factor for the <i>i</i> -th right singular vector.
<i>z</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>k</i>). Contains the components of the deflation-adjusted updating row vector.
<i>K</i>	INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.
<i>c</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if <i>sqre</i> = 0 and the <i>c</i> value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>s</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if <i>sqre</i> = 0 and the <i>s</i> value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>work</i>	REAL for slals0 DOUBLE PRECISION for dlals0 Workspace array, DIMENSION (<i>k</i>). Used with real flavors only.
<i>rwork</i>	REAL for clals0 DOUBLE PRECISION for zlals0

Workspace array, `DIMENSION` ($k*(1+nrhs) + 2*nrhs$). Used with complex flavors only.

Output Parameters

`b` On exit, contains the solution X in rows 1 through n .

`info` INTEGER.
 If `info` = 0: successful exit.
 If `info` = $-i < 0$, the i -th argument had an illegal value.

?lalsa

Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd.

Syntax

```
call slalsa( icompg, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
call dlalsa( icompg, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
call clalsa( icompg, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork, info )
call zlalsa( icompg, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl, difr, z,
poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork, info )
```

Include Files

- `mkl.fi`

Description

The routine is an intermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form. The singular vectors are computed as products of simple orthogonal matrices.

If `icompg` = 0, ?lalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if `icompg` = 1, the routine applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in the compact form by ?lalsa.

Input Parameters

`icompg` INTEGER. Specifies whether the left or the right singular vector matrix is involved. If `icompg` = 0: left singular vector matrix is used
 If `icompg` = 1: right singular vector matrix is used.

`smlsiz` INTEGER. The maximum size of the subproblems at the bottom of the computation tree.

`n` INTEGER. The row and column dimensions of the upper bidiagonal matrix.

<i>nrhs</i>	INTEGER. The number of columns of <i>b</i> and <i>bx</i> . Must be at least 1.
<i>b</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa DOUBLE COMPLEX for zlalsa Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). Contains the right hand sides of the least squares problem in rows 1 through <i>m</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, \max(m, n))$.
<i>ldbx</i>	INTEGER. The leading dimension of the output array <i>bx</i> .
<i>u</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i>). On entry, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>ldu</i>	INTEGER, $ldu \geq n$. The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> .
<i>vt</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i> + 1). On entry, <i>vt</i> ^T (for real flavors) or <i>vt</i> ^H (for complex flavors) contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	INTEGER array, DIMENSION (<i>n</i>).
<i>difl</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>nlvl</i>), where $nlvl = \text{int}(\log_2(n / (smlsiz+1))) + 1$.
<i>difr</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , $2*nlvl$). On entry, <i>difl</i> (*, <i>i</i>) and <i>difr</i> (*, $2i-1$) record distances between singular values on the <i>i</i> -th level and singular values on the (<i>i</i> -1)-th level, and <i>difr</i> (*, $2i$) record the normalizing factors of the right singular vectors matrices of subproblems on <i>i</i> -th level.
<i>z</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>nlvl</i>). On entry, <i>z</i> (1, <i>i</i>) contains the components of the deflation- adjusted updating the row vector for subproblems on the <i>i</i> -th level.

<i>poles</i>	<p>REAL for slalsa/clalsa</p> <p>DOUBLE PRECISION for dlalsa/zlalsa</p> <p>Array, DIMENSION (<i>Idu</i>, 2*<i>nlvl</i>).</p> <p>On entry, <i>poles</i>(*, 2<i>i</i>-1: 2<i>i</i>) contains the new and old singular values involved in the secular equations on the <i>i</i>-th level.</p>
<i>givptr</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>).</p> <p>On entry, <i>givptr</i>(<i>i</i>) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.</p>
<i>givcol</i>	<p>INTEGER. Array, DIMENSION (<i>ldgcol</i>, 2*<i>nlvl</i>). On entry, for each <i>i</i>, <i>givcol</i>(*, 2<i>i</i>-1: 2<i>i</i>) records the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>ldgcol</i>	<p>INTEGER, <i>ldgcol</i> ≥ <i>n</i>. The leading dimension of arrays <i>givcol</i> and <i>perm</i>.</p>
<i>perm</i>	<p>INTEGER. Array, DIMENSION (<i>ldgcol</i>, <i>nlvl</i>). On entry, <i>perm</i>(*, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.</p>
<i>givnum</i>	<p>REAL for slalsa/clalsa</p> <p>DOUBLE PRECISION for dlalsa/zlalsa</p> <p>Array, DIMENSION (<i>Idu</i>, 2*<i>nlvl</i>). On entry, <i>givnum</i>(*, 2<i>i</i>-1 : 2<i>i</i>) records the <i>c</i> and <i>s</i> values of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>c</i>	<p>REAL for slalsa/clalsa</p> <p>DOUBLE PRECISION for dlalsa/zlalsa</p> <p>Array, DIMENSION (<i>n</i>). On entry, if the <i>i</i>-th subproblem is not square, <i>c</i>(<i>i</i>) contains the <i>c</i> value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.</p>
<i>s</i>	<p>REAL for slalsa/clalsa</p> <p>DOUBLE PRECISION for dlalsa/zlalsa</p> <p>Array, DIMENSION (<i>n</i>). On entry, if the <i>i</i>-th subproblem is not square, <i>s</i>(<i>i</i>) contains the <i>s</i>-value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.</p>
<i>work</i>	<p>REAL for slalsa</p> <p>DOUBLE PRECISION for dlalsa</p> <p>Workspace array, DIMENSION at least (<i>n</i>). Used with real flavors only.</p>
<i>rwork</i>	<p>REAL for clalsa</p> <p>DOUBLE PRECISION for zlalsa</p> <p>Workspace array, DIMENSION at least max(<i>n</i>, (<i>smlsz</i>+1) * <i>nrhs</i> * 3). Used with complex flavors only.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION at least (3<i>n</i>).</p>

Output Parameters

<i>b</i>	On exit, contains the solution X in rows 1 through n .
<i>bx</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa DOUBLE COMPLEX for zlalsa Array, DIMENSION (<i>ldbx</i> , <i>nrhs</i>). On exit, the result of applying the left or right singular vector matrix to <i>b</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value.

?lalsd

Uses the singular value decomposition of A to solve the least squares problem.

Syntax

```
call slalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork, info )
call dlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork, info )
call clalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork, iwork, info )
call zlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork, iwork, info )
```

Include Files

- mkl.fi

Description

The routine uses the singular value decomposition of A to solve the least squares problem of finding X to minimize the Euclidean norm of each column of A^*X-B , where A is n -by- n upper bidiagonal, and X and B are n -by- $nrhs$. The solution X overwrites B .

The singular values of A smaller than $rcond$ times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in d in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.

It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Input Parameters

<i>uplo</i>	CHARACTER*1. If <i>uplo</i> = 'U', d and e define an upper bidiagonal matrix.
-------------	--

If *uplo* = 'L', *d* and *e* define a lower bidiagonal matrix.

<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The dimension of the bidiagonal matrix. $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of columns of <i>B</i> . Must be at least 1.
<i>d</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i> -1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>b</i>	REAL for slalsd DOUBLE PRECISION for dlalsd COMPLEX for clalsd DOUBLE COMPLEX for zlalsd Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). On input, <i>b</i> contains the right hand sides of the least squares problem. On output, <i>b</i> contains the solution <i>X</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, n)$.
<i>rcond</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd The singular values of <i>A</i> less than or equal to <i>rcond</i> times the largest singular value are treated as zero in solving the least squares problem. If <i>rcond</i> is negative, machine precision is used instead. For example, for the least squares problem $\text{diag}(S) * X = B$, where $\text{diag}(S)$ is a diagonal matrix of singular values, the solution is $X(i) = B(i) / S(i)$ if $S(i)$ is greater than $rcond * \max(S)$, and $X(i) = 0$ if $S(i)$ is less than or equal to $rcond * \max(S)$.
<i>rank</i>	INTEGER. The number of singular values of <i>A</i> greater than <i>rcond</i> times the largest singular value.
<i>work</i>	REAL for slalsd DOUBLE PRECISION for dlalsd COMPLEX for clalsd DOUBLE COMPLEX for zlalsd

Workspace array.

DIMENSION for real flavors at least

$(9n + 2n * smlsiz + 8n * nlvl + n * nrhs + (smlsiz + 1)^2)$,

where

$nlvl = \max(0, \text{int}(\log_2(n / (smlsiz + 1))) + 1)$.

DIMENSION for complex flavors is $(n * nrhs)$.

rwork

REAL for clalsd

DOUBLE PRECISION for zlalsd

Workspace array, used with complex flavors only.

DIMENSION at least $(9n + 2n * smlsiz + 8n * nlvl + 3 * mlsiz * nrhs + (smlsiz + 1)^2)$,

where

$nlvl = \max(0, \text{int}(\log_2(\min(m, n) / (smlsiz + 1))) + 1)$.

iwork

INTEGER.

Workspace array of DIMENSION $(3n * nlvl + 11n)$.

Output Parameters

d

On exit, if *info* = 0, *d* contains singular values of the bidiagonal matrix.

e

On exit, destroyed.

b

On exit, *b* contains the solution *X*.

info

INTEGER.

If *info* = 0: successful exit.

If *info* = -*i* < 0, the *i*-th argument had an illegal value.

If *info* > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns *info*/(*n*+1) through mod(*info*, *n*+1).

?lamrg

Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.

Syntax

call slamrg(*n1*, *n2*, *a*, *strd1*, *strd2*, *index*)

call dlamrg(*n1*, *n2*, *a*, *strd1*, *strd2*, *index*)

Include Files

- mkl.fi

Description

The routine creates a permutation list which will merge the elements of a (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Input Parameters

$n1, n2$	INTEGER. These arguments contain the respective lengths of the two sorted lists to be merged.
a	REAL for <code>slamrg</code> DOUBLE PRECISION for <code>dlamrg</code> . Array, DIMENSION $(n1+n2)$. The first $n1$ elements of a contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final $n2$ elements.
$strd1, strd2$	INTEGER. These are the strides to be taken through the array a . Allowable strides are 1 and -1. They indicate whether a subset of a is sorted in ascending ($strdx = 1$) or descending ($strdx = -1$) order.

Output Parameters

$index$	INTEGER. Array, DIMENSION $(n1+n2)$. On exit, this array will contain a permutation such that if $b(i) = a(index(i))$ for $i=1, n1+n2$, then b will be sorted in ascending order.
---------	--

?laneg

*Computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T - $\sigma I = L^*D^*L^T$.*

Syntax

```
value = slaneq( n, d, lld, sigma, pivmin, r )
```

```
value = dlaneg( n, d, lld, sigma, pivmin, r )
```

Include Files

- `mk1.fi`

Description

The routine computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal T - $\sigma I = L^*D^*L^T$. This implementation works directly on the factors without forming the tridiagonal matrix T . The Sturm count is also the number of eigenvalues of T less than σ . This routine is called from `?larb`. The current routine does not use the `pivmin` parameter but rather requires IEEE-754 propagation of infinities and NaNs (NaN stands for 'Not A Number'). This routine also has no input range restrictions but does require default exception handling such that $x/0$ produces `Inf` when x is non-zero, and `Inf/Inf` produces `NaN`. (For more information see [Marques06]).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
<i>d</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the matrix <i>D</i> .
<i>lld</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (<i>n</i> -1). Contains (<i>n</i> -1) elements $L(i) * L(i) * D(i)$.
<i>sigma</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Shift amount in $T - \sigma * I = L * D * L^* * T$.
<i>pivmin</i>	REAL for slaneg DOUBLE PRECISION for dlaneg The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.
<i>r</i>	INTEGER. The twist index for the twisted factorization that is used for the negcount.

Output Parameters

<i>value</i>	INTEGER. The number of negative pivots encountered while factoring.
--------------	---

?langb

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.

Syntax

```
val = slangb( norm, n, kl, ku, ab, ldab, work )
val = dlangb( norm, n, kl, ku, ab, ldab, work )
val = clangb( norm, n, kl, ku, ab, ldab, work )
val = zlangb( norm, n, kl, ku, ab, ldab, work )
```

Include Files

- mkl.fi

Description

The function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n band matrix A , with kl sub-diagonals and ku super-diagonals.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>?langb</i> is set to zero.</p>
<i>kl</i>	<p>INTEGER. The number of sub-diagonals of the matrix A. $kl \geq 0$.</p>
<i>ku</i>	<p>INTEGER. The number of super-diagonals of the matrix A. $ku \geq 0$.</p>
<i>ab</i>	<p>REAL for <i>slangb</i></p> <p>DOUBLE PRECISION for <i>dlangb</i></p> <p>COMPLEX for <i>clangb</i></p> <p>DOUBLE COMPLEX for <i>zlangb</i></p> <p>Array, DIMENSION (<i>ldab</i>,<i>n</i>).</p> <p>The band matrix A, stored in rows 1 to $kl+ku+1$. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows:</p> $ab(ku+1+i-j, j) = a(i, j)$ <p>for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of the array <i>ab</i>.</p> <p>$ldab \geq kl+ku+1$.</p>
<i>work</i>	<p>REAL for <i>slangb/clangb</i></p> <p>DOUBLE PRECISION for <i>dlangb/zlangb</i></p> <p>Workspace array, DIMENSION ($\max(1, lwork)$), where</p> <p>$lwork \geq n$ when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.</p>

Output Parameters

<i>val</i>	<p>REAL for <i>slangb/clangb</i></p> <p>DOUBLE PRECISION for <i>dlangb/zlangb</i></p> <p>Value returned by the function.</p>
------------	--

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
val = slange( norm, m, n, a, lda, work )
val = dlange( norm, m, n, a, lda, work )
val = clange( norm, m, n, a, lda, work )
val = zlange( norm, m, n, a, lda, work )
```

Include Files

- mkl.fi

Description

The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix A.

Input Parameters

The data types are given for the Fortran interface.

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>m</i>	<p>INTEGER. The number of rows of the matrix A.</p> <p>$m \geq 0$. When $m = 0$, ?lange is set to zero.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A.</p> <p>$n \geq 0$. When $n = 0$, ?lange is set to zero.</p>
<i>a</i>	<p>REAL for slange</p> <p>DOUBLE PRECISION for dlange</p> <p>COMPLEX for clange</p> <p>DOUBLE COMPLEX for zlange</p> <p>Array, DIMENSION (<i>lda</i>,<i>n</i>).</p> <p>Array <i>a</i> contains the <i>m</i>-by-<i>n</i> matrix A.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p>

work REAL for slange and clange.
 DOUBLE PRECISION for dlange and zlange.
 Workspace array, DIMENSION $\max(1, lwork)$, where $lwork \geq m$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slange/clange
 DOUBLE PRECISION for dlange/zlange
 Value returned by the function.

?langt

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.

Syntax

```
val = slangt( norm, n, dl, d, du )
val = dlangt( norm, n, dl, d, du )
val = clangt( norm, n, dl, d, du )
val = zlangt( norm, n, dl, d, du )
```

Include Files

- mkl.fi

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex tridiagonal matrix *A*.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix *A*.
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix *A* (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix *A* (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix *A* (square root of sum of squares).

n INTEGER. The order of the matrix *A*. $n \geq 0$. When $n = 0$, ?langt is set to zero.

dl, d, du REAL for slangt

DOUBLE PRECISION for dlangt

COMPLEX for clangt

DOUBLE COMPLEX for zlangt

Arrays: dl ($n-1$), d (n), du ($n-1$).

The array dl contains the ($n-1$) sub-diagonal elements of A .

The array d contains the diagonal elements of A .

The array du contains the ($n-1$) super-diagonal elements of A .

Output Parameters

val REAL for slangt/clangt
DOUBLE PRECISION for dlangt/zlangt
Value returned by the function.

?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.

Syntax

```
val = slanh( norm, n, a, lda, work )
val = dlanh( norm, n, a, lda, work )
val = clanh( norm, n, a, lda, work )
val = zlanhs( norm, n, a, lda, work )
```

Include Files

- mkl.fi

Description

The function ?lanhs returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A .

The value *val* returned by the function is:

```
val = max(abs(Aij)), if norm = 'M' or 'm'
= norm1(A), if norm = '1' or 'O' or 'o'
= normI(A), if norm = 'I' or 'i'
= normF(A), if norm = 'F', 'f', 'E' or 'e'
```

where `norm1` denotes the 1-norm of a matrix (maximum column sum), `normI` denotes the infinity norm of a matrix (maximum row sum) and `normF` denotes the Frobenius norm of a matrix (square root of sum of squares). Note that `max(abs(Aij))` is not a consistent matrix norm.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine as described above.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$. When $n = 0$, <i>?lanhs</i> is set to zero.
<i>a</i>	REAL for <i>slanhs</i> DOUBLE PRECISION for <i>dlanhs</i> COMPLEX for <i>clanhs</i> DOUBLE COMPLEX for <i>zlanhs</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). The <i>n</i> -by- <i>n</i> upper Hessenberg matrix <i>A</i> ; the part of <i>A</i> below the first sub-diagonal is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(n, 1)$.
<i>work</i>	REAL for <i>slanhs</i> and <i>clanhs</i> . DOUBLE PRECISION for <i>dlanhs</i> and <i>zlanhs</i> . Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq n$ when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for <i>slanhs</i> / <i>clanhs</i> DOUBLE PRECISION for <i>dlanhs</i> / <i>zlanhs</i> Value returned by the function.
------------	---

?lansb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.

Syntax

```
val = slansb( norm, uplo, n, k, ab, ldab, work )
val = dlansb( norm, uplo, n, k, ab, ldab, work )
val = clansb( norm, uplo, n, k, ab, ldab, work )
val = zlansb( norm, uplo, n, k, ab, ldab, work )
```

Include Files

- mkl.fi

Description

The function `?lansb` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real/complex symmetric band matrix A , with k super-diagonals.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the band matrix A is supplied. If <i>uplo</i> = 'U': upper triangular part is supplied; If <i>uplo</i> = 'L': lower triangular part is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p> <p>When $n = 0$, <code>?lansb</code> is set to zero.</p>

Output Parameters

val REAL for slansb/clansb
DOUBLE PRECISION for dlansb/zlansb
Value returned by the function.

?lanhb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.

Syntax

```
val = clanhb( norm, uplo, n, k, ab, ldab, work )
val = zlanhb( norm, uplo, n, k, ab, ldab, work )
```

Include Files

- mkl.fi

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n Hermitian band matrix A , with k super-diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo CHARACTER*1.
Specifies whether the upper or lower triangular part of the band matrix A is supplied.
If *uplo* = 'U': upper triangular part is supplied;
If *uplo* = 'L': lower triangular part is supplied.

n INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, ?lanhb is set to zero.

k INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A .
 $k \geq 0$.

ab COMPLEX for clanhb.

DOUBLE COMPLEX for zlanhb.

Array, DIMENSION ($ldaB, n$). The upper or lower triangle of the Hermitian band matrix A , stored in the first $k+1$ rows of ab . The j -th column of A is stored in the j -th column of the array ab as follows:

if $uplo = 'U'$, $ab(k+1+i-j, j) = a(i, j)$

for $\max(1, j-k) \leq i \leq j$;

if $uplo = 'L'$, $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

$ldab$

INTEGER. The leading dimension of the array ab . $ldab \geq k+1$.

$work$

REAL for clanhb.

DOUBLE PRECISION for zlanhb.

Workspace array, DIMENSION $\max(1, lwork)$, where

$lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, $work$ is not referenced.

Output Parameters

val

REAL for slanhb/clanhb

DOUBLE PRECISION for dlanhb/zlanhb

Value returned by the function.

?lansp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.

Syntax

$val = slansp(norm, uplo, n, ap, work)$

$val = dlansp(norm, uplo, n, ap, work)$

$val = clansp(norm, uplo, n, ap, work)$

$val = zlansp(norm, uplo, n, ap, work)$

Include Files

- mkl.fi

Description

The function ?lansp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A , supplied in packed form.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix A is supplied.</p> <p>If <i>uplo</i> = 'U': Upper triangular part of A is supplied</p> <p>If <i>uplo</i> = 'L': Lower triangular part of A is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>slansp</i> is set to zero.</p>
<i>ap</i>	<p>REAL for <i>slansp</i></p> <p>DOUBLE PRECISION for <i>dlansp</i></p> <p>COMPLEX for <i>clansp</i></p> <p>DOUBLE COMPLEX for <i>zlansp</i></p> <p>Array, DIMENSION $(n(n+1)/2)$.</p> <p>The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array <i>ap</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;</p> <p>if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.</p>
<i>work</i>	<p>REAL for <i>slansp</i> and <i>clansp</i>.</p> <p>DOUBLE PRECISION for <i>dlansp</i> and <i>zlansp</i>.</p> <p>Workspace array, DIMENSION $(\max(1, lwork))$, where $lwork \geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.</p>

Output Parameters

<i>val</i>	<p>REAL for <i>slansp/clansp</i></p> <p>DOUBLE PRECISION for <i>dlansp/zlansp</i></p> <p>Value returned by the function.</p>
------------	--

?lanhp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.

Syntax

```
val = clanhp( norm, uplo, n, ap, work )
val = zlanhp( norm, uplo, n, ap, work )
```

Include Files

- mkl.fi

Description

The function ?lanhp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A , supplied in packed form.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix A is supplied.</p> <p>If <i>uplo</i> = 'U': Upper triangular part of A is supplied</p> <p>If <i>uplo</i> = 'L': Lower triangular part of A is supplied.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A.</p> <p>$n \geq 0$. When $n = 0$, ?lanhp is set to zero.</p>
<i>ap</i>	<p>COMPLEX for clanhp.</p> <p>DOUBLE COMPLEX for zlanhp.</p> <p>Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array <i>ap</i> as follows:</p> <ul style="list-style-type: none"> if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.
<i>work</i>	<p>REAL for clanhp.</p>

DOUBLE PRECISION for zlanhp.

Workspace array, DIMENSION (max(1, lwork)), where

$lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, $work$ is not referenced.

Output Parameters

val

REAL for clanhp.

DOUBLE PRECISION for zlanhp.

Value returned by the function.

?lanst/?lanht

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.

Syntax

val = slanst(*norm*, *n*, *d*, *e*)

val = dlanst(*norm*, *n*, *d*, *e*)

val = clanht(*norm*, *n*, *d*, *e*)

val = zlanht(*norm*, *n*, *d*, *e*)

Include Files

- mkl.fi

Description

The functions ?lanst/?lanht return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or a complex Hermitian tridiagonal matrix A .

Input Parameters

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .

= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),

= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),

= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

n

INTEGER. The order of the matrix A .

$n \geq 0$. When $n = 0$, ?lanst/?lanht is set to zero.

d

REAL for slanst/clanht

DOUBLE PRECISION for dlanst/zlanht

Array, DIMENSION (n). The diagonal elements of A .

e

REAL for slanst

DOUBLE PRECISION for dlanst

COMPLEX for clanht

DOUBLE COMPLEX for zlanht

Array, DIMENSION ($n-1$).

The ($n-1$) sub-diagonal or super-diagonal elements of A .

Output Parameters

val

REAL for slanst/clanht

DOUBLE PRECISION for dlanst/zlanht

Value returned by the function.

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

```
val = slansy( norm, uplo, n, a, lda, work )
```

```
val = dlansy( norm, uplo, n, a, lda, work )
```

```
val = clansy( norm, uplo, n, a, lda, work )
```

```
val = zlansy( norm, uplo, n, a, lda, work )
```

Include Files

- mkl.fi

Description

The function ?lansy returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A .

Input Parameters

The data types are given for the Fortran interface.

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': val = max(abs(A_{ij})), largest absolute value of the matrix A .

= '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum),

= 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum),

= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced.

= 'U': Upper triangular part of A is referenced.

= 'L': Lower triangular part of A is referenced

n

INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, `?lansy` is set to zero.

a

REAL for slansy

DOUBLE PRECISION for dlansy

COMPLEX for clansy

DOUBLE COMPLEX for zlansy

Array, size (lda, n) . The symmetric matrix A .

If *uplo* = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If *uplo* = 'L', the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda

INTEGER. The leading dimension of the array a .

$lda \geq \max(n, 1)$.

work

REAL for slansy and clansy.

DOUBLE PRECISION for dlansy and zlansy.

Workspace array, DIMENSION $(\max(1, lwork))$, where

$lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, $work$ is not referenced.

Output Parameters

val

REAL for slansy/clansy

DOUBLE PRECISION for dlansy/zlansy

Value returned by the function.

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

$val = \text{clanhe}(norm, uplo, n, a, lda, work)$

```
val = zlanhe( norm, uplo, n, a, lda, work )
```

Include Files

- mkl.fi

Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A .

Input Parameters

The data types are given for the Fortran interface.

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix A is to be referenced.</p> <p>= 'U': Upper triangular part of A is referenced.</p> <p>= 'L': Lower triangular part of A is referenced</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <code>?lanhe</code> is set to zero.</p>
<i>a</i>	<p>COMPLEX for <code>clanhe</code>.</p> <p>DOUBLE COMPLEX for <code>zlanhe</code>.</p> <p>Array, size (lda, n). The Hermitian matrix A.</p> <p>If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of a contains the upper triangular part of the matrix A, and the strictly lower triangular part of a is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of a contains the lower triangular part of the matrix A, and the strictly upper triangular part of a is not referenced.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array a.</p> <p>$lda \geq \max(n, 1)$.</p>
<i>work</i>	<p>REAL for <code>clanhe</code>.</p> <p>DOUBLE PRECISION for <code>zlanhe</code>.</p> <p>Workspace array, $\text{DIMENSION}(\max(1, lwork))$, where</p>

$lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, $work$ is not referenced.

Output Parameters

val REAL for `clanhe`.
 DOUBLE PRECISION for `zlanhe`.
 Value returned by the function.

?lantb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.

Syntax

```
val = slantb( norm, uplo, diag, n, k, ab, ldab, work )
val = dlantb( norm, uplo, diag, n, k, ab, ldab, work )
val = clantb( norm, uplo, diag, n, k, ab, ldab, work )
val = zlantb( norm, uplo, diag, n, k, ab, ldab, work )
```

Include Files

- `mkl.fi`

Description

The function `?lantb` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n triangular band matrix A , with $(k + 1)$ diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo CHARACTER*1.
 Specifies whether the matrix A is upper or lower triangular.
 = 'U': Upper triangular
 = 'L': Lower triangular.

diag CHARACTER*1.

Specifies whether or not the matrix A is unit triangular.

= 'N': Non-unit triangular

= 'U': Unit triangular.

n INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, *?lantb* is set to zero.

k INTEGER. The number of super-diagonals of the matrix A if *uplo* = 'U', or the number of sub-diagonals of the matrix A if *uplo* = 'L'. $k \geq 0$.

ab REAL for slantb
DOUBLE PRECISION for dlantb
COMPLEX for clantb
DOUBLE COMPLEX for zlantb

Array, DIMENSION (*ldab*,*n*). The upper or lower triangular band matrix A , stored in the first $k+1$ rows of *ab*.

The j -th column of A is stored in the j -th column of the array *ab* as follows:

if *uplo* = 'U', $ab(k+1+i-j, j) = a(i, j)$ for $\max(1, j-k) \leq i \leq j$;

if *uplo* = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.

Note that when *diag* = 'U', the elements of the array *ab* corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq k+1$.

work REAL for slantb and clantb.
DOUBLE PRECISION for dlantb and zlantb.
Workspace array, DIMENSION ($\max(1, lwork)$), where
 $lwork \geq n$ when *norm* = 'I' ; otherwise, *work* is not referenced.

Output Parameters

val REAL for slantb/clantb.
DOUBLE PRECISION for dlantb/zlantb.
Value returned by the function.

?lantp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.

Syntax

val = slantp(*norm*, *uplo*, *diag*, *n*, *ap*, *work*)

```

val = dlantp( norm, uplo, diag, n, ap, work )
val = clantp( norm, uplo, diag, n, ap, work )
val = zlantp( norm, uplo, diag, n, ap, work )

```

Include Files

- mkl.fi

Description

The function `?lantp` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A , supplied in packed form.

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the matrix A is upper or lower triangular.</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular.</p>
<i>diag</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not the matrix A is unit triangular.</p> <p>= 'N': Non-unit triangular</p> <p>= 'U': Unit triangular.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A.</p> <p>$n \geq 0$. When $n = 0$, <code>?lantp</code> is set to zero.</p>
<i>ap</i>	<p>REAL for <code>slantp</code></p> <p>DOUBLE PRECISION for <code>dlantp</code></p> <p>COMPLEX for <code>clantp</code></p> <p>DOUBLE COMPLEX for <code>zlantp</code></p> <p>Array, DIMENSION $(n(n+1)/2)$.</p> <p>The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array <i>ap</i> as follows:</p> <p>if <i>uplo</i> = 'U', $AP(i + (j-1)j/2) = a(i, j)$ for $1 \leq i \leq j$;</p> <p>if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = a(i, j)$ for $j \leq i \leq n$.</p>

Note that when *diag* = 'U', the elements of the array *ap* corresponding to the diagonal elements of the matrix *A* are not referenced, but are assumed to be one.

work

REAL for slantp and clantp.

DOUBLE PRECISION for dlantp and zlantp.

Workspace array, DIMENSION(max(1, *lwork*)), where *lwork* ≥ *n* when *norm* = 'I' ; otherwise, *work* is not referenced.

Output Parameters

val

REAL for slantp/clantp.

DOUBLE PRECISION for dlantp/zlantp.

Value returned by the function.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
val = slantr( norm, uplo, diag, m, n, a, lda, work )
```

```
val = dlantr( norm, uplo, diag, m, n, a, lda, work )
```

```
val = clantr( norm, uplo, diag, m, n, a, lda, work )
```

```
val = zlantr( norm, uplo, diag, m, n, a, lda, work )
```

Include Files

- mkl.fi

Description

The function ?lantr returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix *A*.

Input Parameters

The data types are given for the Fortran interface.

norm

CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': *val* = max(abs(*A*_{*ij*})), largest absolute value of the matrix *A*.

= '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the matrix A is upper or lower trapezoidal.</p> <p>= 'U': Upper trapezoidal</p> <p>= 'L': Lower trapezoidal.</p> <p>Note that A is triangular instead of trapezoidal if $m = n$.</p>
<i>diag</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not the matrix A has unit diagonal.</p> <p>= 'N': Non-unit diagonal</p> <p>= 'U': Unit diagonal.</p>
<i>m</i>	<p>INTEGER. The number of rows of the matrix A. $m \geq 0$, and if <i>uplo</i> = 'U', $m \leq n$.</p> <p>When $m = 0$, <i>?lantr</i> is set to zero.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A. $n \geq 0$, and if <i>uplo</i> = 'L', $n \leq m$.</p> <p>When $n = 0$, <i>?lantr</i> is set to zero.</p>
<i>a</i>	<p>REAL for <i>slantr</i></p> <p>DOUBLE PRECISION for <i>dlantr</i></p> <p>COMPLEX for <i>clantr</i></p> <p>DOUBLE COMPLEX for <i>zlantr</i></p> <p>Array, DIMENSION (<i>lda</i>,<i>n</i>).</p> <p>The trapezoidal matrix A (A is triangular if $m = n$).</p> <p>If <i>uplo</i> = 'U', the leading m-by-n upper trapezoidal part of the array <i>a</i> contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading m-by-n lower trapezoidal part of the array <i>a</i> contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when <i>diag</i> = 'U', the diagonal elements of A are not referenced and are assumed to be one.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>.</p> <p>$lda \geq \max(m, 1)$.</p>
<i>work</i>	<p>REAL for <i>slantr/clantrp</i>.</p> <p>DOUBLE PRECISION for <i>dlantr/zlantr</i>.</p> <p>Workspace array, DIMENSION ($\max(1, lwork)$), where</p> <p>$lwork \geq m$ when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.</p>

Output Parameters

<i>val</i>	REAL for <i>slantr/clantrp</i> .
------------	----------------------------------

DOUBLE PRECISION for dlantr/zlantr.

Value returned by the function.

?lanv2

Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.

Syntax

```
call slantv2( a, b, c, d, rtlr, rtli, rt2r, rt2i, cs, sn )
```

```
call dlanv2( a, b, c, d, rtlr, rtli, rt2r, rt2i, cs, sn )
```

Include Files

- mkl.fi

Description

The routine computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} cs & -sn \\ sn & cs \end{bmatrix} \begin{bmatrix} aa & bb \\ cc & dd \end{bmatrix} \begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix}$$

where either

1. $cc = 0$ so that aa and dd are real eigenvalues of the matrix, or
2. $aa = dd$ and $bb*cc < 0$, so that $aa \pm \sqrt{bb*cc}$ are complex conjugate eigenvalues.

The routine was adjusted to reduce the risk of cancellation errors, when computing real eigenvalues, and to ensure, if possible, that $\text{abs}(rtlr) \geq \text{abs}(rt2r)$.

Input Parameters

a, b, c, d REAL for slantv2
DOUBLE PRECISION for dlanv2.
On entry, elements of the input matrix.

Output Parameters

a, b, c, d On exit, overwritten by the elements of the standardized Schur form.

$rtlr, rtli, rt2r, rt2i$ REAL for slantv2
DOUBLE PRECISION for dlanv2.
The real and imaginary parts of the eigenvalues.
If the eigenvalues are a complex conjugate pair, $rtli > 0$.

cs, sn REAL for slantv2
DOUBLE PRECISION for dlanv2.

Parameters of the rotation matrix.

?lapll

Measures the linear dependence of two vectors.

Syntax

```
call slapll( n, x, incx, Y, incy, ssmin )
call dlapll( n, x, incx, Y, incy, ssmin )
call clapll( n, x, incx, Y, incy, ssmin )
call zlapll( n, x, incx, Y, incy, ssmin )
```

Include Files

- mkl.fi

Description

Given two column vectors x and y of length n , let

$A = (xy)$ be the n -by-2 matrix.

The routine ?lapll first computes the QR factorization of A as $A = Q \cdot R$ and then computes the SVD of the 2-by-2 upper triangular matrix R . The smaller singular value of R is returned in *ssmin*, which is used as the measurement of the linear dependency of the vectors x and y .

Input Parameters

n	INTEGER. The length of the vectors x and y .
x	REAL for slapll DOUBLE PRECISION for dlapll COMPLEX for clapll DOUBLE COMPLEX for zlapll Array, DIMENSION $(1+(n-1)incx)$. On entry, x contains the n -vector x .
y	REAL for slapll DOUBLE PRECISION for dlapll COMPLEX for clapll DOUBLE COMPLEX for zlapll Array, DIMENSION $(1+(n-1)incy)$. On entry, y contains the n -vector y .
$incx$	INTEGER. The increment between successive elements of x ; $incx > 0$.
$incy$	INTEGER. The increment between successive elements of y ; $incy > 0$.

Output Parameters

x	On exit, x is overwritten.
y	On exit, y is overwritten.
$ssmin$	REAL for <code>slapll/clapll</code> DOUBLE PRECISION for <code>dlapll/zlapll</code> The smallest singular value of the n -by-2 matrix $A = (xy)$.

?lapmr

Rearranges rows of a matrix as specified by a permutation vector.

Syntax

```
call slapmr( forwr, m, n, x, ldx, k )
call dlapmr( forwr, m, n, x, ldx, k )
call clapmr( forwr, m, n, x, ldx, k )
call zlapmr( forwr, m, n, x, ldx, k )
call lapmr( x, k[, forwr] )
```

Include Files

- `mkl.fi`

Description

The `?lapmr` routine rearranges the rows of the m -by- n matrix X as specified by the permutation $k(1), k(2), \dots, k(m)$ of the integers $1, \dots, m$.

If `forwr` = `.TRUE.`, forward permutation:

$X(k(i), *)$ is moved to $X(i, *)$ for $i = 1, 2, \dots, m$.

If `forwr` = `.FALSE.`, backward permutation:

$X(i, *)$ is moved to $X(k(i), *)$ for $i = 1, 2, \dots, m$.

Input Parameters

The data types are given for the Fortran interface.

$forwr$	LOGICAL. If <code>forwr</code> = <code>.TRUE.</code> , forward permutation. If <code>forwr</code> = <code>.FALSE.</code> , backward permutation.
m	INTEGER. The number of rows of the matrix X . $m \geq 0$.
n	INTEGER. The number of columns of the matrix X . $n \geq 0$.
x	REAL for <code>slapmr</code> DOUBLE PRECISION for <code>dlapmr</code>

COMPLEX for `clapmr`

DOUBLE COMPLEX for `zlapmr`

Array, size (ldx, n) On entry, the m -by- n matrix X .

ldx INTEGER. The leading dimension of the array X , $ldx \geq \max(1, m)$.

k INTEGER. Array, size (m) . On entry, k contains the permutation vector and is used as internal workspace.

Output Parameters

x On exit, x contains the permuted matrix X .

k On exit, k is reset to its original value.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `?lapmr` interface are as follows:

x Holds the matrix X of size (n, n) .

k Holds the vector of length m .

*forwr*d Specifies the permutation. Must be `'.TRUE.'` or `'.FALSE.'`.

See Also

`?lapmt`

?lapmt

Performs a forward or backward permutation of the columns of a matrix.

Syntax

```
call slapmt( forwr, m, n, x, ldx, k )
```

```
call dlapmt( forwr, m, n, x, ldx, k )
```

```
call clapmt( forwr, m, n, x, ldx, k )
```

```
call zlapmt( forwr, m, n, x, ldx, k )
```

Include Files

- `mkl.fi`

Description

The routine `?lapmt` rearranges the columns of the m -by- n matrix X as specified by the permutation $k(1), k(2), \dots, k(n)$ of the integers $1, \dots, n$.

If *forwr* = `.TRUE.`, forward permutation:

$X(*, k(j))$ is moved to $X(*, j)$ for $j=1, 2, \dots, n$.

If *forwr* = `.FALSE.`, backward permutation:

$X(*, j)$ is moved to $X(*, k(j))$ for $j = 1, 2, \dots, n$.

Input Parameters

<i>forwrd</i>	LOGICAL. If <i>forwrd</i> = .TRUE., forward permutation If <i>forwrd</i> = .FALSE., backward permutation
<i>m</i>	INTEGER. The number of rows of the matrix <i>X</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>X</i> . $n \geq 0$.
<i>x</i>	REAL for slapmt DOUBLE PRECISION for dlapmt COMPLEX for clapmt DOUBLE COMPLEX for zlapmt Array, DIMENSION (<i>ldx</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>X</i> .
<i>ldx</i>	INTEGER. The leading dimension of the array <i>X</i> , $ldx \geq \max(1, m)$.
<i>k</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, <i>k</i> contains the permutation vector and is used as internal workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> contains the permuted matrix <i>X</i> .
<i>k</i>	On exit, <i>k</i> is reset to its original value.

?lapy2

Returns $\sqrt{x^2+y^2}$.

Syntax

val = slapy2(*x*, *y*)

val = dlapy2(*x*, *y*)

Include Files

- mkl.fi

Description

The function ?lapy2 returns $\sqrt{x^2+y^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

The data types are given for the Fortran interface.

<i>x</i> , <i>y</i>	REAL for slapy2
---------------------	-----------------

DOUBLE PRECISION for `dlapy2`

Specify the input values x and y .

Output Parameters

`val`

REAL for `slapy2`

DOUBLE PRECISION for `dlapy2`.

Value returned by the function.

If `val=-1D0`, the first argument was NaN.

If `val=-2D0`, the second argument was NaN.

?lapy3

Returns $\sqrt{x^2+y^2+z^2}$.

Syntax

`val = slapy3(x, y, z)`

`val = dlapy3(x, y, z)`

Include Files

- `mkl.fi`

Description

The function `?lapy3` returns $\sqrt{x^2+y^2+z^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

The data types are given for the Fortran interface.

x, y, z

REAL for `slapy3`

DOUBLE PRECISION for `dlapy3`

Specify the input values x, y and z .

Output Parameters

`val`

REAL for `slapy3`

DOUBLE PRECISION for `dlapy3`.

Value returned by the function.

If `val = -1D0`, the first argument was NaN.

If `val = -2D0`, the second argument was NaN.

If `val = -3D0`, the third argument was NaN.

?laqgb

Scales a general band matrix, using row and column scaling factors computed by `?gbequ`.

Syntax

```
call slaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call dlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call claqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call zlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

Include Files

- mkl.fi

Description

The routine equilibrates a general m -by- n band matrix A with kl subdiagonals and ku superdiagonals using the row and column scaling factors in the vectors r and c .

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A . $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A . $ku \geq 0$.
ab	REAL for slaqgb DOUBLE PRECISION for dlaqgb COMPLEX for claqgb DOUBLE COMPLEX for zlaqgb Array, DIMENSION ($ldab, n$). On entry, the matrix A in band storage, in rows 1 to $kl+ku+1$. The j -th column of A is stored in the j -th column of the array ab as follows: $ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
$ldab$	INTEGER. The leading dimension of the array ab . $lda \geq kl+ku+1$.
$amax$	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Absolute value of largest matrix entry.
r, c	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Arrays $r(m)$, $c(n)$. Contain the row and column scale factors for A , respectively.
$rowcnd$	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Ratio of the smallest $r(i)$ to the largest $r(i)$.

colcnd REAL for slaqgb/claqgb
 DOUBLE PRECISION for dlaqgb/zlaqgb
 Ratio of the smallest $c(i)$ to the largest $c(i)$.

Output Parameters

ab On exit, the equilibrated matrix, in the same storage format as A .
 See *equed* for the form of the equilibrated matrix.

equed CHARACTER*1.
 Specifies the form of equilibration that was done.
 If *equed* = 'N': No equilibration
 If *equed* = 'R': Row equilibration, that is, A has been premultiplied by $\text{diag}(r)$.
 If *equed* = 'C': Column equilibration, that is, A has been postmultiplied by $\text{diag}(c)$.
 If *equed* = 'B': Both row and column equilibration, that is, A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If $\text{rowcnd} < \text{thresh}$, row scaling is done, and if $\text{colcnd} < \text{thresh}$, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, row scaling is done.

?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ.

Syntax

```
call slaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call dlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call claqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call zlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
```

Include Files

- mkl.fi

Description

The routine equilibrates a general m -by- n matrix A using the row and column scaling factors in the vectors r and c .

Input Parameters

m INTEGER. The number of rows of the matrix A .

	$m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
a	REAL for <code>slaqge</code> DOUBLE PRECISION for <code>dlaqge</code> COMPLEX for <code>claqge</code> DOUBLE COMPLEX for <code>zlaqge</code> Array, DIMENSION (lda, n). On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(m, 1)$.
r	REAL for <code>slanqge/claqge</code> DOUBLE PRECISION for <code>dlaqge/zlaqge</code> Array, DIMENSION (m). The row scale factors for A .
c	REAL for <code>slanqge/claqge</code> DOUBLE PRECISION for <code>dlaqge/zlaqge</code> Array, DIMENSION (n). The column scale factors for A .
$rowcnd$	REAL for <code>slanqge/claqge</code> DOUBLE PRECISION for <code>dlaqge/zlaqge</code> Ratio of the smallest $r(i)$ to the largest $r(i)$.
$colcnd$	REAL for <code>slanqge/claqge</code> DOUBLE PRECISION for <code>dlaqge/zlaqge</code> Ratio of the smallest $c(i)$ to the largest $c(i)$.
$amax$	REAL for <code>slanqge/claqge</code> DOUBLE PRECISION for <code>dlaqge/zlaqge</code> Absolute value of largest matrix entry.

Output Parameters

a	On exit, the equilibrated matrix. See <i>equed</i> for the form of the equilibrated matrix.
<i>equed</i>	CHARACTER*1. Specifies the form of equilibration that was done. If <i>equed</i> = 'N': No equilibration If <i>equed</i> = 'R': Row equilibration, that is, A has been premultiplied by $\text{diag}(r)$.

If *equed* = 'C': Column equilibration, that is, *A* has been postmultiplied by *diag(c)*.

If *equed* = 'B': Both row and column equilibration, that is, *A* has been replaced by *diag(r)*A*diag(c)*.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If *rowcnd* < *thresh*, row scaling is done, and if *colcnd* < *thresh*, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, row scaling is done.

?laqhb

Scales a Hermetian band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call claqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

```
call zlaqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Include Files

- mkl.fi

Description

The routine equilibrates a Hermetian band matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix <i>A</i> if <i>uplo</i> = 'U', or the number of sub-diagonals if <i>uplo</i> = 'L'. $kd \geq 0$.
<i>ab</i>	COMPLEX for claqhb DOUBLE COMPLEX for zlaqhb Array, DIMENSION (<i>ldab</i> , <i>n</i>). On entry, the upper or lower triangle of the band matrix <i>A</i> , stored in the first <i>kd</i> +1 rows of the array. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows:

if *uplo* = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;
 if *uplo* = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab INTEGER. The leading dimension of the array *ab*.
ldab $\geq kd+1$.

scond REAL for *claqsb*
 DOUBLE PRECISION for *zlaqsb*
 Ratio of the smallest $s(i)$ to the largest $s(i)$.

amax REAL for *claqsb*
 DOUBLE PRECISION for *zlaqsb*
 Absolute value of largest matrix entry.

Output Parameters

ab On exit, if *info* = 0, the triangular factor *U* or *L* from the Cholesky factorization $A = U^H * U$ or $A = L * L^H$ of the band matrix *A*, in the same storage format as *A*.

s REAL for *claqsb*
 DOUBLE PRECISION for *zlaqsb*
 Array, DIMENSION (*n*). The scale factors for *A*.

equed CHARACTER*1.
 Specifies whether or not equilibration was done.
 If *equed* = 'N': No equilibration.
 If *equed* = 'Y': Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done.

The values *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqp2

Computes a QR factorization with column pivoting of the matrix block.

Syntax

```
call slaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call dlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call claqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call zlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
```

Include Files

- `mk1.fi`

Description

The routine computes a *QR* factorization with column pivoting of the block $A(offset+1:m, 1:n)$. The block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>offset</i>	INTEGER. The number of rows of the matrix <i>A</i> that must be pivoted but not factorized. $offset \geq 0$.
<i>a</i>	REAL for <code>slaqp2</code> DOUBLE PRECISION for <code>dlaqp2</code> COMPLEX for <code>claqp2</code> DOUBLE COMPLEX for <code>zlaqp2</code> Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, if $jpvt(i) \neq 0$, the <i>i</i> -th column of <i>A</i> is permuted to the front of <i>A*P</i> (a leading column); if $jpvt(i) = 0$, the <i>i</i> -th column of <i>A</i> is a free column.
<i>vn1, vn2</i>	REAL for <code>slaqp2/claqp2</code> DOUBLE PRECISION for <code>dlaqp2/zlaqp2</code> Arrays, DIMENSION (<i>n</i>) each. Contain the vectors with the partial and exact column norms, respectively.
<i>work</i>	REAL for <code>slaqp2</code> DOUBLE PRECISION for <code>dlaqp2</code> COMPLEX for <code>claqp2</code> DOUBLE COMPLEX for <code>zlaqp2</code> Workspace array, DIMENSION (<i>n</i>).

Output Parameters

<i>a</i>	On exit, the upper triangle of block $A(offset+1:m, 1:n)$ is the triangular factor obtained; the elements in block $A(offset+1:m, 1:n)$ below the diagonal, together with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors. Block $A(1:offset, 1:n)$ has been accordingly pivoted, but not factorized.
----------	---

<i>jpvt</i>	On exit, if $jpvt(i) = k$, then the i -th column of A^*P was the k -th column of A .
<i>tau</i>	REAL for slaqp2 DOUBLE PRECISION for dlaqp2 COMPLEX for claqp2 DOUBLE COMPLEX for zlaqp2 Array, DIMENSION(min(m , n)). The scalar factors of the elementary reflectors.
<i>vn1, vn2</i>	Contain the vectors with the partial and exact column norms, respectively.

?laqps

Computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3.

Syntax

```
call slaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call dlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call claqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
call zlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf )
```

Include Files

- mkl.fi

Description

The routine computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3. The routine tries to factorize NB columns from A starting from the row $offset+1$, and updates all of the matrix with BLAS level 3 routine ?gemm.

In some cases, due to catastrophic cancellations, ?laqps cannot factorize NB columns. Hence, the actual number of factorized columns is returned in kb .

Block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>offset</i>	INTEGER. The number of rows of A that have been factorized in previous steps.
<i>nb</i>	INTEGER. The number of columns to factorize.
<i>a</i>	REAL for slaqps DOUBLE PRECISION for dlaqps

COMPLEX for claqp3

DOUBLE COMPLEX for zlaqp3

Array, DIMENSION (lda, n).

On entry, the m -by- n matrix A .

lda INTEGER. The leading dimension of the array a .

$lda \geq \max(1, m)$.

jpvt INTEGER. Array, DIMENSION (n).

If $jpvt(i) = k$ then column k of the full matrix A has been permuted into position i in AP.

vn1, vn2 REAL for slaqp3/claqp3

DOUBLE PRECISION for dlaqp3/zlaqp3

Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.

auxv REAL for slaqp3

DOUBLE PRECISION for dlaqp3

COMPLEX for claqp3

DOUBLE COMPLEX for zlaqp3

Array, DIMENSION (nb). Auxiliary vector.

f REAL for slaqp3

DOUBLE PRECISION for dlaqp3

COMPLEX for claqp3

DOUBLE COMPLEX for zlaqp3

Array, DIMENSION (ldf, nb). For real flavors, matrix $F^T = L * Y^T * A$. For complex flavors, matrix $F^H = L * Y^H * A$.

ldf INTEGER. The leading dimension of the array f .

$ldf \geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns actually factorized.

a On exit, block $A(offset+1:m, 1:kb)$ is the triangular factor obtained and block $A(1:offset, 1:n)$ has been accordingly pivoted, but not factorized. The rest of the matrix, block $A(offset+1:m, kb+1:n)$ has been updated.

jpvt INTEGER array, DIMENSION (n). If $jpvt(i) = k$ then column k of the full matrix A has been permuted into position i in AP.

tau REAL for slaqp3

DOUBLE PRECISION for dlaqp3

	COMPLEX for claqpz
	DOUBLE COMPLEX for zlaqpz
	Array, DIMENSION (kb). The scalar factors of the elementary reflectors.
vn1, vn2	The vectors with the partial and exact column norms, respectively.
auxv	Auxiliary vector.
f	Matrix $F' = L*Y'*A$.

?laqr0

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```
call slaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )
call dlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )
call claqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )
call zlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )
```

Include Files

- mkl.fi

Description

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H=Z*T*Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q*H*Q^H = (QZ)*H*(QZ)^H$.

Input Parameters

wantt	LOGICAL. If wantt = .TRUE., the full Schur form T is required; If wantt = .FALSE., only eigenvalues are required.
wantz	LOGICAL. If wantz = .TRUE., the matrix of Schur vectors Z is required; If wantz = .FALSE., Schur vectors are not required.
n	INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).

<i>ilo, ihi</i>	<p>INTEGER.</p> <p>It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $H(ilo, ilo-1) = 0$.</p> <p>ilo and ihi are normally set by a previous call to <code>cgebal</code>, and then passed to <code>cgehrd</code> when the matrix output by <code>cgebal</code> is reduced to Hessenberg form. Otherwise, ilo and ihi should be set to 1 and n, respectively.</p> <p>If $n > 0$, then $1 \leq ilo \leq ihi \leq n$.</p> <p>If $n=0$, then $ilo=1$ and $ihi=0$</p>
<i>h</i>	<p>REAL for <code>slaqr0</code></p> <p>DOUBLE PRECISION for <code>dlaqr0</code></p> <p>COMPLEX for <code>claqr0</code></p> <p>DOUBLE COMPLEX for <code>zlaqr0</code>.</p> <p>Array, DIMENSION (ldh, n), contains the upper Hessenberg matrix H.</p>
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> . $ldh \geq \max(1, n)$.
<i>iloz, ihiz</i>	<p>INTEGER. Specify the rows of Z to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>, $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.</p>
<i>z</i>	<p>REAL for <code>slaqr0</code></p> <p>DOUBLE PRECISION for <code>dlaqr0</code></p> <p>COMPLEX for <code>claqr0</code></p> <p>DOUBLE COMPLEX for <code>zlaqr0</code>.</p> <p>Array, DIMENSION (ldz, ihi), contains the matrix Z if <i>wantz</i> is <code>.TRUE.</code>. If <i>wantz</i> is <code>.FALSE.</code>, z is not referenced.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array <i>z</i>.</p> <p>If <i>wantz</i> is <code>.TRUE.</code>, then $ldz \geq \max(1, ihiz)$. Otherwise, $ldz \geq 1$.</p>
<i>work</i>	<p>REAL for <code>slaqr0</code></p> <p>DOUBLE PRECISION for <code>dlaqr0</code></p> <p>COMPLEX for <code>claqr0</code></p> <p>DOUBLE COMPLEX for <code>zlaqr0</code>.</p> <p>Workspace array with dimension <i>lwork</i>.</p>
<i>lwork</i>	<p>INTEGER. The dimension of the array <i>work</i>.</p> <p>$lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$.</p> <p>It is recommended to use the workspace query to determine the optimal workspace size. If $lwork=-1$, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input</p>

parameters n , ilo , and ihi . The estimate is returned in $work(1)$. No error messages related to the $lwork$ is issued by `xerbla`. Neither H nor Z are accessed.

Output Parameters

h	<p>If $info=0$, and $wantt$ is <code>.TRUE.</code>, then h contains the upper quasi-triangular/triangular matrix T from the Schur decomposition (the Schur form).</p> <p>If $info=0$, and $wantt$ is <code>.FALSE.</code>, then the contents of h are unspecified on exit.</p> <p>(The output values of h when $info > 0$ are given under the description of the $info$ parameter below.)</p> <p>The routine may explicitly set $h(i, j)$ for $i > j$ and $j=1, 2, \dots, ilo-1$ or $j=ihi+1, ihi+2, \dots, n$.</p>
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
w	<p>COMPLEX for <code>claqr0</code></p> <p>DOUBLE COMPLEX for <code>zlaqr0</code>.</p> <p>Arrays, <code>DIMENSION(n)</code>. The computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in $w(ilo:ihi)$. If $wantt$ is <code>.TRUE.</code>, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h, with $w(i) = h(i, i)$.</p>
wr, wi	<p>REAL for <code>slaqr0</code></p> <p>DOUBLE PRECISION for <code>dlaqr0</code></p> <p>Arrays, <code>DIMENSION(ihi)</code> each. The real and imaginary parts, respectively, of the computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in $wr(ilo:ihi)$ and $wi(ilo:ihi)$. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi, say the i-th and $(i+1)$-th, with $wi(i) > 0$ and $wi(i+1) < 0$. If $wantt$ is <code>.TRUE.</code>, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h, with $wr(i) = h(i, i)$, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then $wi(i) = \sqrt{-h(i+1, i) * h(i, i+1)}$.</p>
z	<p>If $wantz$ is <code>.TRUE.</code>, then $z(ilo:ihi, iloz:ihiz)$ is replaced by $z(ilo:ihi, iloz:ihiz) * U$, where U is the orthogonal/unitary Schur factor of $h(ilo:ihi, ilo:ihi)$.</p> <p>If $wantz$ is <code>.FALSE.</code>, z is not referenced.</p> <p>(The output values of z when $info > 0$ are given under the description of the $info$ parameter below.)</p>
$info$	<p>INTEGER.</p> <p>= 0: the execution is successful.</p> <p>> 0: if $info = i$, then the routine failed to compute all the eigenvalues. Elements $1:ilo-1$ and $i+1:n$ of wr and wi contain those eigenvalues which have been successfully computed.</p>

> 0: if *wantt* is `.FALSE.`, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is `.TRUE.`, then (initial value of *h*)**U* = *U**(final value of *h*, where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is `.TRUE.`, then (final value of *z*(*ilo:ihi*, *iloz:ihiz*))=(initial value of *z*(*ilo:ihi*, *iloz:ihiz*))**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is `.FALSE.`, then *z* is not accessed.

?laqr1

Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix *H* and specified shifts.

Syntax

```
call slaqr1( n, h, ldh, sr1, si1, sr2, si2, v )
call dlaqr1( n, h, ldh, sr1, si1, sr2, si2, v )
call claqr1( n, h, ldh, s1, s2, v )
call zlaqr1( n, h, ldh, s1, s2, v )
```

Include Files

- mkl.fi

Description

Given a 2-by-2 or 3-by-3 matrix *H*, this routine sets *v* to a scalar multiple of the first column of the product

$K = (H - s1*I)*(H - s2*I)$, or $K = (H - (sr1 + i*si1)*I)*(H - (sr2 + i*si2)*I)$

scaling to avoid overflows and most underflows.

It is assumed that either 1) *sr1* = *sr2* and *si1* = -*si2*, or 2) *si1* = *si2* = 0.

This is useful for starting double implicit shift bulges in the QR algorithm.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>H</i> . <i>n</i> must be equal to 2 or 3.
<i>sr1, si2, sr2, si2</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 Shift values that define <i>K</i> in the formula above.
<i>s1, s2</i>	COMPLEX for claqr1 DOUBLE COMPLEX for zlaqr1.

Shift values that define K in the formula above.

h REAL for slaqr1
DOUBLE PRECISION for dlaqr1
COMPLEX for claqr1
DOUBLE COMPLEX for zlaqr1.
Array, DIMENSION (ldh, n), contains 2-by-2 or 3-by-3 matrix H in the formula above.

ldh INTEGER.
The leading dimension of the array h just as declared in the calling routine.
 $ldh \geq n$.

Output Parameters

v REAL for slaqr1
DOUBLE PRECISION for dlaqr1
COMPLEX for claqr1
DOUBLE COMPLEX for zlaqr1.
Array with dimension (n).
A scalar multiple of the first column of the matrix K in the formula above.

?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

The routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

This subroutine is identical to `?laqr3` except that it avoids recursion by calling `?lahqr` instead of `?laqr4`.

Input Parameters

<code>wantt</code>	LOGICAL. If <code>wantt = .TRUE.</code> , then the Hessenberg matrix H is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine). If <code>wantt = .FALSE.</code> , then only enough of H is updated to preserve the eigenvalues.
<code>wantz</code>	LOGICAL. If <code>wantz = .TRUE.</code> , then the orthogonal/unitary matrix Z is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine). If <code>wantz = .FALSE.</code> , then Z is not referenced.
<code>n</code>	INTEGER. The order of the Hessenberg matrix H and (if <code>wantz = .TRUE.</code>) the order of the orthogonal/unitary matrix Z .
<code>ktop</code>	INTEGER. It is assumed that either <code>ktop=1</code> or <code>h(ktop,ktop-1)=0</code> . <code>ktop</code> and <code>kbot</code> together determine an isolated block along the diagonal of the Hessenberg matrix.
<code>kbot</code>	INTEGER. It is assumed without a check that either <code>kbot=n</code> or <code>h(kbot+1,kbot)=0</code> . <code>ktop</code> and <code>kbot</code> together determine an isolated block along the diagonal of the Hessenberg matrix.
<code>nw</code>	INTEGER. Size of the deflation window. $1 \leq nw \leq (kbot-ktop+1)$.
<code>h</code>	REAL for <code>slaqr2</code> DOUBLE PRECISION for <code>dlaqr2</code> COMPLEX for <code>claqr2</code> DOUBLE COMPLEX for <code>zlaqr2</code> . Array, DIMENSION (<code>ldh</code> , <code>n</code>), on input the initial n -by- n section of h stores the Hessenberg matrix H undergoing aggressive early deflation.
<code>ldh</code>	INTEGER. The leading dimension of the array h just as declared in the calling subroutine. $ldh \geq n$.
<code>iloz, ihiz</code>	INTEGER. Specify the rows of Z to which transformations must be applied if <code>wantz</code> is <code>.TRUE.</code> . $1 \leq iloz \leq ihiz \leq n$.

<i>z</i>	<p>REAL for slaqr2</p> <p>DOUBLE PRECISION for dlaqr2</p> <p>COMPLEX for claqr2</p> <p>DOUBLE COMPLEX for zlaqr2.</p> <p>Array, DIMENSION (<i>ldz</i>, <i>n</i>), contains the matrix <i>Z</i> if <i>wantz</i> is .TRUE.. If <i>wantz</i> is .FALSE., then <i>z</i> is not referenced.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling subroutine. $ldz \geq 1$.</p>
<i>v</i>	<p>REAL for slaqr2</p> <p>DOUBLE PRECISION for dlaqr2</p> <p>COMPLEX for claqr2</p> <p>DOUBLE COMPLEX for zlaqr2.</p> <p>Workspace array with dimension (<i>ldv</i>, <i>nw</i>). An <i>nw</i>-by-<i>nw</i> work array.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling subroutine. $ldv \geq nw$.</p>
<i>nh</i>	<p>INTEGER. The number of column of <i>t</i>. $nh \geq nw$.</p>
<i>t</i>	<p>REAL for slaqr2</p> <p>DOUBLE PRECISION for dlaqr2</p> <p>COMPLEX for claqr2</p> <p>DOUBLE COMPLEX for zlaqr2.</p> <p>Workspace array with dimension (<i>ldt</i>, <i>nw</i>).</p>
<i>ldt</i>	<p>INTEGER. The leading dimension of the array <i>t</i> just as declared in the calling subroutine. $ldt \geq nw$.</p>
<i>nv</i>	<p>INTEGER. The number of rows of work array <i>wv</i> available for workspace. $nv \geq nw$.</p>
<i>wv</i>	<p>REAL for slaqr2</p> <p>DOUBLE PRECISION for dlaqr2</p> <p>COMPLEX for claqr2</p> <p>DOUBLE COMPLEX for zlaqr2.</p> <p>Workspace array with dimension (<i>ldwv</i>, <i>nw</i>).</p>
<i>ldwv</i>	<p>INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling subroutine. $ldwv \geq nw$.</p>
<i>work</i>	<p>REAL for slaqr2</p> <p>DOUBLE PRECISION for dlaqr2</p> <p>COMPLEX for claqr2</p>

DOUBLE COMPLEX for `zlaqr2`.

Workspace array with dimension *lwork*.

lwork

INTEGER. The dimension of the array *work*.

lwork=2**nw*) is sufficient, but for the optimal performance a greater workspace may be required.

If *lwork*=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters *n*, *nw*, *ktop*, and *kbot*. The estimate is returned in *work*(1). No error messages related to the *lwork* is issued by `xerbla`. Neither *H* nor *Z* are accessed.

Output Parameters

h

On output *h* has been transformed by an orthogonal/unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

work(1)

On exit *work*(1) is set to an estimate of the optimal value of *lwork* for the given values of the input parameters *n*, *nw*, *ktop*, and *kbot*.

z

If *wantz* is `.TRUE.`, then the orthogonal/unitary similarity transformation is accumulated into *z*(*iloz:ihiz*, *ilo:ihi*) from the right.

If *wantz* is `.FALSE.`, then *z* is unreferenced.

nd

INTEGER. The number of converged eigenvalues uncovered by the routine.

ns

INTEGER. The number of unconverged, that is approximate eigenvalues returned in *sr*, *si* or in *sh* that may be used as shifts by the calling subroutine.

sh

COMPLEX for `claqr2`

DOUBLE COMPLEX for `zlaqr2`.

Arrays, DIMENSION (*kbot*).

The approximate eigenvalues that may be used for shifts are stored in the *sh*(*kbot*-*nd*-*ns*+1) through the *sh*(*kbot*-*nd*).

The converged eigenvalues are stored in the *sh*(*kbot*-*nd*+1) through the *sh*(*kbot*).

sr, *si*

REAL for `slaqr2`

DOUBLE PRECISION for `dlaqr2`

Arrays, DIMENSION (*kbot*) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the *sr*(*kbot*-*nd*-*ns*+1) through the *sr*(*kbot*-*nd*), and *si*(*kbot*-*nd*-*ns*+1) through the *si*(*kbot*-*nd*), respectively.

The real and imaginary parts of converged eigenvalues are stored in the *sr*(*kbot*-*nd*+1) through the *sr*(*kbot*), and *si*(*kbot*-*nd*+1) through the *si*(*kbot*), respectively.

?laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sr,
si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns, nd, sh,
v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```
call slaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )

call dlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz, work,
lwork, info )

call claqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )

call zlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work, lwork,
info )
```

Include Files

- `mkl.fi`

Description

The routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^* H^* Q^H = (QZ)^* H^* (QZ)^H$.

This routine implements one level of recursion for `?laqr0`. It is a complete implementation of the small bulge multi-shift QR algorithm. It may be called by `?laqr0` and, for large enough deflation window size, it may be called by `?laqr3`. This routine is identical to `?laqr0` except that it calls `?laqr2` instead of `?laqr3`.

Input Parameters

<i>wantt</i>	<p>LOGICAL.</p> <p>If <i>wantt</i> = <code>.TRUE.</code>, the full Schur form <i>T</i> is required;</p> <p>If <i>wantt</i> = <code>.FALSE.</code>, only eigenvalues are required.</p>
<i>wantz</i>	<p>LOGICAL.</p> <p>If <i>wantz</i> = <code>.TRUE.</code>, the matrix of Schur vectors <i>Z</i> is required;</p> <p>If <i>wantz</i> = <code>.FALSE.</code>, Schur vectors are not required.</p>
<i>n</i>	<p>INTEGER. The order of the Hessenberg matrix <i>H</i>. ($n \geq 0$).</p>
<i>ilo, ihi</i>	<p>INTEGER.</p> <p>It is assumed that <i>H</i> is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $h(ilo, ilo-1) = 0$.</p> <p><i>ilo</i> and <i>ihi</i> are normally set by a previous call to <code>cgebal</code>, and then passed to <code>cgehrd</code> when the matrix output by <code>cgebal</code> is reduced to Hessenberg form. Otherwise, <i>ilo</i> and <i>ihi</i> should be set to 1 and <i>n</i>, respectively.</p> <p>If $n > 0$, then $1 \leq ilo \leq ihi \leq n$.</p> <p>If $n=0$, then $ilo=1$ and $ihi=0$</p>
<i>h</i>	<p>REAL for slaqr4</p> <p>DOUBLE PRECISION for dlaqr4</p> <p>COMPLEX for claqr4</p> <p>DOUBLE COMPLEX for zlaqr4.</p> <p>Array, DIMENSION (<i>ldh</i>, <i>n</i>), contains the upper Hessenberg matrix <i>H</i>.</p>
<i>ldh</i>	<p>INTEGER. The leading dimension of the array <i>h</i>. $ldh \geq \max(1, n)$.</p>
<i>iloz, ihiz</i>	<p>INTEGER. Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>, $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.</p>
<i>z</i>	<p>REAL for slaqr4</p> <p>DOUBLE PRECISION for dlaqr4</p> <p>COMPLEX for claqr4</p> <p>DOUBLE COMPLEX for zlaqr4.</p> <p>Array, DIMENSION (<i>ldz</i>, <i>ihiz</i>), contains the matrix <i>Z</i> if <i>wantz</i> is <code>.TRUE.</code>. If <i>wantz</i> is <code>.FALSE.</code>, <i>z</i> is not referenced.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the array <i>z</i>.</p> <p>If <i>wantz</i> is <code>.TRUE.</code>, then $ldz \geq \max(1, ihiz)$. Otherwise, $ldz \geq 1$.</p>
<i>work</i>	<p>REAL for slaqr4</p> <p>DOUBLE PRECISION for dlaqr4</p> <p>COMPLEX for claqr4</p>

DOUBLE COMPLEX for `zlaqr4`.

Workspace array with dimension *lwork*.

lwork

INTEGER. The dimension of the array *work*.

$lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6 * n$.

It is recommended to use the workspace query to determine the optimal workspace size. If *lwork*=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters *n*, *ilo*, and *ihi*. The estimate is returned in *work*(1). No error messages related to the *lwork* is issued by `xerbla`. Neither *H* nor *Z* are accessed.

Output Parameters

h

If *info*=0, and *wantt* is `.TRUE.`, then *h* contains the upper quasi-triangular/triangular matrix *T* from the Schur decomposition (the Schur form).

If *info*=0, and *wantt* is `.FALSE.`, then the contents of *h* are unspecified on exit.

(The output values of *h* when *info* > 0 are given under the description of the *info* parameter below.)

The routines may explicitly set *h*(*i*,*j*) for *i*>*j* and *j*=1,2,...*ilo*-1 or *j*=*ihi*+1, *ihi*+2,...*n*.

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

w

COMPLEX for `claqr4`

DOUBLE COMPLEX for `zlaqr4`.

Arrays, DIMENSION(*n*). The computed eigenvalues of *h*(*ilo*:*ihi*, *ilo*:*ihi*) are stored in *w*(*ilo*:*ihi*). If *wantt* is `.TRUE.`, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *w*(*i*) = *h*(*i*,*i*).

wr, *wi*

REAL for `slaqr4`

DOUBLE PRECISION for `dlaqr4`

Arrays, DIMENSION(*ihi*) each. The real and imaginary parts, respectively, of the computed eigenvalues of *h*(*ilo*:*ihi*, *ilo*:*ihi*) are stored in the *wr*(*ilo*:*ihi*) and *wi*(*ilo*:*ihi*). If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0. If *wantt* is `.TRUE.`, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *wr*(*i*) = *h*(*i*,*i*), and if *h*(*i*:*i*+1, *i*:*i*+1) is a 2-by-2 diagonal block, then *wi*(*i*) = sqrt(-*h*(*i*+1, *i*) * *h*(*i*, *i*+1)).

z

If *wantz* is `.TRUE.`, then *z*(*ilo*:*ihi*, *iloz*:*ihiz*) is replaced by *z*(*ilo*:*ihi*, *iloz*:*ihiz*)**U*, where *U* is the orthogonal/unitary Schur factor of *h*(*ilo*:*ihi*, *ilo*:*ihi*).

If *wantz* is `.FALSE.`, *z* is not referenced.

(The output values of *z* when *info* > 0 are given under the description of the *info* parameter below.)

info

INTEGER.

= 0: the execution is successful.

> 0: if *info* = *i*, then the routine failed to compute all the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

> 0: if *wantt* is `.FALSE.`, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is `.TRUE.`, then (initial value of *h*)**U* = *U**(final value of *h*, where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is `.TRUE.`, then (final value of *z*(*ilo*:*ihi*, *iloz*:*ihiz*))=(initial value of *z*(*ilo*:*ihi*, *iloz*:*ihiz*))**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is `.FALSE.`, then *z* is not accessed.

?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
call slaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz, ihiz,
z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call dlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh, iloz, ihiz,
z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call claqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz, ihiz, z,
ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

```
call zlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz, ihiz, z,
ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

Description

This auxiliary routine called by ?laqr0 performs a single small-bulge multi-shift QR sweep.

Input Parameters

wantt

LOGICAL.

	<p><i>wantt</i> = <code>.TRUE.</code> if the quasi-triangular/triangular Schur factor is computed.</p> <p><i>wantt</i> is set to <code>.FALSE.</code> otherwise.</p>
<i>wantz</i>	<p>LOGICAL.</p> <p><i>wantz</i> = <code>.TRUE.</code> if the orthogonal/unitary Schur factor is computed.</p> <p><i>wantz</i> is set to <code>.FALSE.</code> otherwise.</p>
<i>kacc22</i>	<p>INTEGER. Possible values are 0, 1, or 2.</p> <p>Specifies the computation mode of far-from-diagonal orthogonal updates.</p> <p>= 0: the routine does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.</p> <p>= 1: the routine accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.</p> <p>= 2: the routine accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.</p>
<i>n</i>	<p>INTEGER. The order of the Hessenberg matrix <i>H</i> upon which the routine operates.</p>
<i>ktop, kbot</i>	<p>INTEGER.</p> <p>It is assumed without a check that either <i>ktop</i>=1 or <i>h</i>(<i>ktop</i>, <i>ktop</i>-1)=0, and either <i>kbot</i>=<i>n</i> or <i>h</i>(<i>kbot</i>+1, <i>kbot</i>)=0.</p>
<i>nshfts</i>	<p>INTEGER.</p> <p>Number of simultaneous shifts, must be positive and even.</p>
<i>sr, si</i>	<p>REAL for <code>slaqr5</code></p> <p>DOUBLE PRECISION for <code>dlaqr5</code></p> <p>Arrays, DIMENSION (<i>nshfts</i>) each.</p> <p><i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.</p>
<i>s</i>	<p>COMPLEX for <code>claqr5</code></p> <p>DOUBLE COMPLEX for <code>zlaqr5</code>.</p> <p>Arrays, DIMENSION (<i>nshfts</i>).</p> <p><i>s</i> contains the shifts of origin that define the multi-shift QR sweep.</p>
<i>h</i>	<p>REAL for <code>slaqr5</code></p> <p>DOUBLE PRECISION for <code>dlaqr5</code></p> <p>COMPLEX for <code>claqr5</code></p> <p>DOUBLE COMPLEX for <code>zlaqr5</code>.</p> <p>Array, DIMENSION (<i>ldh</i>, <i>n</i>), on input contains the Hessenberg matrix.</p>

<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling routine. $ldh \geq \max(1, n)$.
<i>iloz, ihiz</i>	INTEGER. Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code> . $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Array, DIMENSION (<i>ldz</i> , <i>ihi</i>), contains the matrix <i>Z</i> if <i>wantz</i> is <code>.TRUE.</code> . If <i>wantz</i> is <code>.FALSE.</code> , then <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling routine. $ldz \geq n$.
<i>v</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension (<i>ldv</i> , $nshfts/2$).
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling routine. $ldv \geq 3$.
<i>u</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension (<i>ldu</i> , $3*nshfts-3$).
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> just as declared in the calling routine. $ldu \geq 3*nshfts-3$.
<i>nh</i>	INTEGER. The number of column in the array <i>wh</i> available for workspace. $nh \geq 1$.
<i>wh</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension (<i>ldwh</i> , <i>nh</i>)
<i>ldwh</i>	INTEGER. The leading dimension of the array <i>wh</i> just as declared in the calling routine. $ldwh \geq 3*nshfts-3$

<i>nv</i>	INTEGER. The number of rows of the array <i>wv</i> available for workspace. $nv \geq 1$.
<i>wv</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> DOUBLE COMPLEX for <code>zlaqr5</code> . Workspace array with dimension $(ldwv, 3*nshifts-3)$.
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling routine. $ldwv \geq nv$.

Output Parameters

<i>sr, si</i>	On output, may be reordered.
<i>h</i>	On output a multi-shift QR Sweep with shifts $sr(j)+i*si(j)$ or $s(j)$ is applied to the isolated diagonal block in rows and columns <i>ktop</i> through <i>kbot</i> .
<i>z</i>	If <i>wantz</i> is <code>.TRUE.</code> , then the QR Sweep orthogonal/unitary similarity transformation is accumulated into $z(i_{loz}:i_{hiz}, i_{lo}:i_{hi})$ from the right. If <i>wantz</i> is <code>.FALSE.</code> , then <i>z</i> is unreferenced.

?laqsb

Scales a symmetric band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call slaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call dlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call claqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call zlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Include Files

- `mkl.fi`

Description

The routine equilibrates a symmetric band matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = <code>'U'</code> : upper triangular.
-------------	---

If `uplo = 'L'`: lower triangular.

n INTEGER. The order of the matrix *A*.
 $n \geq 0$.

kd INTEGER. The number of super-diagonals of the matrix *A* if `uplo = 'U'`, or the number of sub-diagonals if `uplo = 'L'`.
 $kd \geq 0$.

ab REAL for slaqsb
DOUBLE PRECISION for dlaqsb
COMPLEX for claqsb
DOUBLE COMPLEX for zlaqsb

Array, DIMENSION (*ldab*,*n*). On entry, the upper or lower triangle of the symmetric band matrix *A*, stored in the first *kd*+1 rows of the array. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:

if `uplo = 'U'`, $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;
if `uplo = 'L'`, $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq kd+1$.

s REAL for slaqsb/claqsb
DOUBLE PRECISION for dlaqsb/zlaqsb
Array, DIMENSION (*n*). The scale factors for *A*.

scond REAL for slaqsb/claqsb
DOUBLE PRECISION for dlaqsb/zlaqsb
Ratio of the smallest *s*(*i*) to the largest *s*(*i*).

amax REAL for slaqsb/claqsb
DOUBLE PRECISION for dlaqsb/zlaqsb
Absolute value of largest matrix entry.

Output Parameters

ab On exit, if `info = 0`, the triangular factor *U* or *L* from the Cholesky factorization of the band matrix *A* that can be $A = U^T * U$ or $A = L * L^T$ for real flavors and $A = U^H * U$ or $A = L * L^H$ for complex flavors, in the same storage format as *A*.

equed CHARACTER*1.
Specifies whether or not equilibration was done.
If `equed = 'N'`: No equilibration.

If *equed* = 'Y': Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $s_{\text{cond}} < \text{thresh}$, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, scaling is done.

?laqsp

Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ.

Syntax

```
call slaqsp( uplo, n, ap, s, scond, amax, equed )
call dlaqsp( uplo, n, ap, s, scond, amax, equed )
call claqsp( uplo, n, ap, s, scond, amax, equed )
call zlaqsp( uplo, n, ap, s, scond, amax, equed )
```

Include Files

Description

The routine ?laqsp equilibrates a symmetric matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored.</p> <p>If <i>uplo</i> = 'U': upper triangular.</p> <p>If <i>uplo</i> = 'L': lower triangular.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>ap</i>	<p>REAL for slaqsp</p> <p>DOUBLE PRECISION for dlaqsp</p> <p>COMPLEX for claqsp</p> <p>DOUBLE COMPLEX for zlaqsp</p> <p>Array, DIMENSION $(n(n+1)/2)$.</p> <p>On entry, the upper or lower triangle of the symmetric matrix <i>A</i>, packed columnwise in a linear array. The <i>j</i>-th column of <i>A</i> is stored in the array <i>ap</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;</p>

	if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.
<i>s</i>	REAL for slaqsp/claqsp DOUBLE PRECISION for dlaqsp/zlaqsp Array, DIMENSION (<i>n</i>). The scale factors for A.
<i>scond</i>	REAL for slaqsp/claqsp DOUBLE PRECISION for dlaqsp/zlaqsp Ratio of the smallest <i>s(i)</i> to the largest <i>s(i)</i> .
<i>amax</i>	REAL for slaqsp/claqsp DOUBLE PRECISION for dlaqsp/zlaqsp Absolute value of largest matrix entry.

Output Parameters

<i>ap</i>	On exit, the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$, in the same storage format as A.
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, that is, A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ.

Syntax

```
call slaqsy( uplo, n, a, lda, s, acond, amax, equed )
call dlaqsy( uplo, n, a, lda, s, acond, amax, equed )
call claqsy( uplo, n, a, lda, s, acond, amax, equed )
call zlaqsy( uplo, n, a, lda, s, acond, amax, equed )
```

Output Parameters

<i>a</i>	<p>On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$.</p>
<i>equed</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not equilibration was done.</p> <p>If <i>equed</i> = 'N': No equilibration.</p>

If `equed = 'Y'`: Equilibration was done, i.e., A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqtr

Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.

Syntax

```
call slaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
call dlaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
```

Include Files

- `mk1.fi`

Description

The routine `?laqtr` solves the real quasi-triangular system

$$\text{op}(T) * p = \text{scale} * c, \text{ if } \text{lreal} = \text{.TRUE.}$$

or the complex quasi-triangular systems

```
op(T + iB)*(p+iq) = scale*(c+id), if lreal = .FALSE.
```

in real arithmetic, where T is upper quasi-triangular.

If $l_{real} = .FALSE.$, then the first diagonal block of T must be 1-by-1, B is the specially structured matrix

.....

$\text{op}(A) = A$ or A^T , A^T denotes the transpose of matrix A .

On input,

[illegible]

This routine is designed for the condition number estimation in routine ?trsna.

Input Parameters

<i>ltran</i>	LOGICAL. On entry, <i>ltran</i> specifies the option of conjugate transpose: = .FALSE., $\text{op}(T + iB) = T + iB$, = .TRUE., $\text{op}(T + iB) = (T + iB)^T$.
<i>lreal</i>	LOGICAL. On entry, <i>lreal</i> specifies the input matrix structure: = .FALSE., the input is complex = .TRUE., the input is real.
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the order of $T + iB$. $n \geq 0$.
<i>t</i>	REAL for slaqtr DOUBLE PRECISION for dlaqtr Array, dimension (ldt, n) . On entry, <i>t</i> contains a matrix in Schur canonical form. If <i>lreal</i> = .FALSE., then the first diagonal block of <i>t</i> must be 1-by-1.
<i>ldt</i>	INTEGER. The leading dimension of the matrix <i>T</i> . $ldt \geq \max(1, n)$.
<i>b</i>	REAL for slaqtr DOUBLE PRECISION for dlaqtr Array, dimension (n) . On entry, <i>b</i> contains the elements to form the matrix <i>B</i> as described above. If <i>lreal</i> = .TRUE., <i>b</i> is not referenced.
<i>w</i>	REAL for slaqtr DOUBLE PRECISION for dlaqtr On entry, <i>w</i> is the diagonal element of the matrix <i>B</i> . If <i>lreal</i> = .TRUE., <i>w</i> is not referenced.
<i>x</i>	REAL for slaqtr DOUBLE PRECISION for dlaqtr Array, dimension $(2n)$. On entry, <i>x</i> contains the right hand side of the system.
<i>work</i>	REAL for slaqtr DOUBLE PRECISION for dlaqtr Workspace array, dimension (n) .

Output Parameters

<i>scale</i>	<p>REAL for <code>slaqtr</code></p> <p>DOUBLE PRECISION for <code>dlaqtr</code></p> <p>On exit, <i>scale</i> is the scale factor.</p>
<i>x</i>	<p>On exit, <i>X</i> is overwritten by the solution.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0: successful exit.</p> <p>If <i>info</i> = 1: the some diagonal 1-by-1 block has been perturbed by a small number <code>smin</code> to keep nonsingularity.</p> <p>If <i>info</i> = 2: the some diagonal 2-by-2 block has been perturbed by a small number in <code>?1aln2</code> to keep nonsingularity.</p>

NOTE

For higher speed, this routine does not check the inputs for errors.

?lar1v

Computes the (scaled) *r*-th column of the inverse of the submatrix in rows *b1* through *bn* of tridiagonal matrix.

Syntax

```
call slar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )

call dlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )

call clar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )

call zlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc, negcnt, ztz,
mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

Include Files

- `mkl.fi`

Description

The routine `?lar1v` computes the (scaled) *r*-th column of the inverse of the submatrix in rows *b1* through *bn* of the tridiagonal matrix $L^*D^*L^T - \lambda^*I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, *r* corresponds to the index where the eigenvector is largest in magnitude.

The following steps accomplish this computation :

- Stationary *qd* transform, $L^*D^*L^T - \lambda^*I = L(+)*D(+)*L(+)^T$
- Progressive *qd* transform, $L^*D^*L^T - \lambda^*I = U(-)*D(-)*U(-)^T$,

- Computation of the diagonal elements of the inverse of $L^*D^*L^T - \lambda^*I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
- Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix $L^*D^*L^T$.
<i>b1</i>	INTEGER. First index of the submatrix of $L^*D^*L^T$.
<i>bn</i>	INTEGER. Last index of the submatrix of $L^*D^*L^T$.
<i>lambda</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The shift. To compute an accurate eigenvector, <i>lambda</i> should be a good approximation to an eigenvalue of $L^*D^*L^T$.
<i>l</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION ($n-1$). The ($n-1$) subdiagonal elements of the unit bidiagonal matrix L , in elements 1 to $n-1$.
<i>d</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (n). The n diagonal elements of the diagonal matrix D .
<i>ld</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION ($n-1$). The $n-1$ elements $L_i^*D_i$.
<i>lld</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION ($n-1$). The $n-1$ elements $L_i^*L_i^*D_i$.
<i>pivmin</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The minimum pivot in the Sturm sequence.
<i>gaptol</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv

Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.

z REAL for slarlv
DOUBLE PRECISION for dlarlv
COMPLEX for clarlv
DOUBLE COMPLEX for zlarlv

Array, DIMENSION (*n*). All entries of *z* must be set to 0.

wantnc LOGICAL.

Specifies whether *negcnt* has to be computed.

r INTEGER.

The twist index for the twisted factorization used to compute *z*. On input, 0 $\leq r \leq n$. If *r* is input as 0, *r* is set to the index where $(L^*D^*L^T - \text{lambda}^*I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, *r* is unchanged.

work REAL for slarlv/clarlv
DOUBLE PRECISION for dlarlv/zlarlv

Workspace array, DIMENSION (4**n*).

Output Parameters

z REAL for slarlv
DOUBLE PRECISION for dlarlv
COMPLEX for clarlv
DOUBLE COMPLEX for zlarlv

Array, DIMENSION (*n*). The (scaled) *r*-th column of the inverse. *z*(*r*) is returned to be 1.

negcnt INTEGER. If *wantnc* is .TRUE. then *negcnt* = the number of pivots < *pivmin* in the matrix factorization $L^*D^*L^T$, and *negcnt* = -1 otherwise.

ztz REAL for slarlv/clarlv
DOUBLE PRECISION for dlarlv/zlarlv

The square of the 2-norm of *z*.

mingma REAL for slarlv/clarlv
DOUBLE PRECISION for dlarlv/zlarlv

The reciprocal of the largest (in magnitude) diagonal element of the inverse of $L^*D^*L^T - \text{lambda}^*I$.

r On output, *r* is the twist index used to compute *z*. Ideally, *r* designates the position of the maximum entry in the eigenvector.

isuppz INTEGER. Array, DIMENSION (2). The support of the vector in *Z*, that is, the vector *z* is nonzero only in elements *isuppz*(1) through *isuppz*(2).

nrminv REAL for slar1v/clar1v
 DOUBLE PRECISION for dlar1v/zlar1v
 Equals $1/\text{sqrt}(ztz)$.

resid REAL for slar1v/clar1v
 DOUBLE PRECISION for dlar1v/zlar1v
 The residual of the FP vector.
 $\text{resid} = \text{ABS}(\text{mingma})/\text{sqrt}(ztz)$.

rqcorr REAL for slar1v/clar1v
 DOUBLE PRECISION for dlar1v/zlar1v
 The Rayleigh Quotient correction to *lambda*.
 $\text{rqcorr} = \text{mingma}/ztz$.

?lar2v

Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.

Syntax

```
call slar2v( n, x, y, z, incx, c, s, incc )
call dlar2v( n, x, y, z, incx, c, s, incc )
call clar2v( n, x, y, z, incx, c, s, incc )
call zlar2v( n, x, y, z, incx, c, s, incc )
```

Include Files

- mkl.fi

Description

The routine ?lar2v applies a vector of real/complex plane rotations with real cosines from both sides to a sequence of 2-by-2 real symmetric or complex Hermitian matrices, defined by the elements of the vectors x, y and z. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} := \begin{bmatrix} c(i) & \text{conjg}(s(i)) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} \begin{bmatrix} c(i) & -\text{conjg}(s(i)) \\ s(i) & c(i) \end{bmatrix}$$

Input Parameters

n INTEGER. The number of plane rotations to be applied.

x, y, z REAL for slar2v
 DOUBLE PRECISION for dlar2v
 COMPLEX for clar2v

DOUBLE COMPLEX for `zlar2v`

Arrays, DIMENSION $(1+(n-1)*incx)$ each. Contain the vectors `x`, `y` and `z`, respectively. For all flavors of `?lar2v`, elements of `x` and `y` are assumed to be real.

`incx` INTEGER. The increment between elements of `x`, `y`, and `z`. `incx` > 0.

`c` REAL for `slar2v/clar2v`

DOUBLE PRECISION for `dlar2v/zlar2v`

Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.

`s` REAL for `slar2v`

DOUBLE PRECISION for `dlar2v`

COMPLEX for `clar2v`

DOUBLE COMPLEX for `zlar2v`

Array, DIMENSION $(1+(n-1)*incc)$. The sines of the plane rotations.

`incc` INTEGER. The increment between elements of `c` and `s`. `incc` > 0.

Output Parameters

`x`, `y`, `z` Vectors `x`, `y` and `z`, containing the results of transform.

?laran

Returns a random real number from a uniform distribution.

Syntax

```
res = slaran (iseed)
```

```
res = dlaran (iseed)
```

Description

The `?laran` routine returns a random real number from a uniform (0,1) distribution. This routine uses a multiplicative congruential method with modulus 2^{48} and multiplier 33952834046453. 48-bit integers are stored in four integer array elements with 12 bits per element. Hence the routine is portable across machines with integers of 32 bits or more.

Input Parameters

`iseed` INTEGER. Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and `iseed(4)` must be odd.

Output Parameters

`iseed` INTEGER.
On exit, the seed is updated.

res REAL for slarf,
DOUBLE PRECISION for dlarf,
Random number.

?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call slarf( side, m, n, v, incv, tau, c, ldc, work )
call dlarf( side, m, n, v, incv, tau, c, ldc, work )
call clarf( side, m, n, v, incv, tau, c, ldc, work )
call zlarf( side, m, n, v, incv, tau, c, ldc, work )
```

Include Files

- mkl.fi

Description

The routine applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in one of the following forms:

- $H = I - \tau v v^T$

where τ is a real scalar and v is a real vector.

If $\tau = 0$, then H is taken to be the unit matrix.

- $H = I - \tau v v^H$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then H is taken to be the unit matrix. For `clarf/zlarf`, to apply H^H (the conjugate transpose of H), supply `conjg(tau)` instead of τ .

Input Parameters

side CHARACTER*1.
If *side* = 'L': form H^*C
If *side* = 'R': form C^*H .

m INTEGER. The number of rows of the matrix C .

n INTEGER. The number of columns of the matrix C .

v REAL for slarf
DOUBLE PRECISION for dlarf
COMPLEX for clarf
DOUBLE COMPLEX for zlarf
Array, DIMENSION

$(1 + (m-1) * \text{abs}(\text{incv}))$ if *side* = 'L' or
 $(1 + (n-1) * \text{abs}(\text{incv}))$ if *side* = 'R'. The vector *v* in the representation of *H*. *v* is not used if *tau* = 0.

incv INTEGER. The increment between elements of *v*.
incv ≠ 0.

tau REAL for slarf
DOUBLE PRECISION for dlarf
COMPLEX for clarf
DOUBLE COMPLEX for zlarf
The value *tau* in the representation of *H*.

c REAL for slarf
DOUBLE PRECISION for dlarf
COMPLEX for clarf
DOUBLE COMPLEX for zlarf
Array, DIMENSION (*ldc*, *n*).
On entry, the *m*-by-*n* matrix *C*.

ldc INTEGER. The leading dimension of the array *c*.
 $ldc \geq \max(1, m)$.

work REAL for slarf
DOUBLE PRECISION for dlarf
COMPLEX for clarf
DOUBLE COMPLEX for zlarf
Workspace array, DIMENSION
(*n*) if *side* = 'L' or
(*m*) if *side* = 'R'.

Output Parameters

c On exit, *C* is overwritten by the matrix H^*C if *side* = 'L', or C^*H if *side* = 'R'.

?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

call slarfb(*side*, *trans*, *direct*, *storev*, *m*, *n*, *k*, *v*, *ldv*, *t*, *ldt*, *c*, *ldc*, *work*, *ldwork*)

```
call dlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

```
call clarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

```
call zlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

Include Files

- mkl.fi

Description

The real flavors of the routine `?larfb` apply a real block reflector H or its transpose H^T to a real m -by- n matrix C from either left or right.

The complex flavors of the routine `?larfb` apply a complex block reflector H or its conjugate transpose H^H to a complex m -by- n matrix C from either left or right.

Input Parameters

The data types are given for the Fortran interface.

<i>side</i>	<p>CHARACTER*1.</p> <p>If <i>side</i> = 'L': apply H or H^T for real flavors and H or H^H for complex flavors from the left.</p> <p>If <i>side</i> = 'R': apply H or H^T for real flavors and H or H^H for complex flavors from the right.</p>
<i>trans</i>	<p>CHARACTER*1.</p> <p>If <i>trans</i> = 'N': apply H (No transpose).</p> <p>If <i>trans</i> = 'C': apply H^H (Conjugate transpose).</p> <p>If <i>trans</i> = 'T': apply H^T (Transpose).</p>
<i>direct</i>	<p>CHARACTER*1.</p> <p>Indicates how H is formed from a product of elementary reflectors</p> <p>If <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward)</p> <p>If <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)</p>
<i>storev</i>	<p>CHARACTER*1.</p> <p>Indicates how the vectors which define the elementary reflectors are stored:</p> <p>If <i>storev</i> = 'C': Column-wise</p> <p>If <i>storev</i> = 'R': Row-wise</p>
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>k</i>	INTEGER. The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector).

<i>v</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>DOUBLE COMPLEX for zlarfb</p> <p>Array, DIMENSION</p> <p>(<i>ldv</i>, <i>k</i>) if <i>storev</i> = 'C'</p> <p>(<i>ldv</i>, <i>m</i>) if <i>storev</i> = 'R' and <i>side</i> = 'L'</p> <p>(<i>ldv</i>, <i>n</i>) if <i>storev</i> = 'R' and <i>side</i> = 'R'</p> <p>The matrix <i>v</i>. See <i>Application Notes</i> below.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i>.</p> <p>If <i>storev</i> = 'C' and <i>side</i> = 'L', $ldv \geq \max(1, m)$;</p> <p>if <i>storev</i> = 'C' and <i>side</i> = 'R', $ldv \geq \max(1, n)$;</p> <p>if <i>storev</i> = 'R', $ldv \geq k$.</p>
<i>t</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>DOUBLE COMPLEX for zlarfb</p> <p>Array, size (<i>ldt</i>, <i>k</i>).</p> <p>Contains the triangular <i>k</i>-by-<i>k</i> matrix <i>T</i> in the representation of the block reflector.</p>
<i>ldt</i>	<p>INTEGER. The leading dimension of the array <i>t</i>.</p> <p>$ldt \geq k$.</p>
<i>c</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>DOUBLE COMPLEX for zlarfb</p> <p>Array, size (<i>ldc</i>, <i>n</i>).</p> <p>On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.</p>
<i>ldc</i>	<p>INTEGER. The leading dimension of the array <i>c</i>.</p> <p>$ldc \geq \max(1, m)$.</p>
<i>work</i>	<p>REAL for slarfb</p> <p>DOUBLE PRECISION for dlarfb</p> <p>COMPLEX for clarfb</p> <p>DOUBLE COMPLEX for zlarfb</p> <p>Workspace array, DIMENSION (<i>ldwork</i>, <i>k</i>).</p>

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

[illegible]
$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$
$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call slarfg( n, alpha, x, incx, tau )
call dlarfg( n, alpha, x, incx, tau )
call clarfg( n, alpha, x, incx, tau )
call zlarfg( n, alpha, x, incx, tau )
```

Include Files

- mkl.fi

Description

The routine ?larfg generates a real/complex elementary reflector H of order n , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^T H = I, \quad \text{for real flavors and}$$

$$H^H \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^H H = I, \quad \text{for complex flavors,}$$

where α and β are scalars (with β real for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^H \end{bmatrix} \quad \text{for complex flavors,}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector, respectively. Note that for clarfg/zlarfg, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $|\text{abs}(\tau) - 1| \leq 1$ (for complex flavors).

Input Parameters

The data types are given for the Fortran interface.

n	INTEGER. The order of the elementary reflector.
α	REAL for slarfg
	DOUBLE PRECISION for dlarfg
	COMPLEX for clarfg

	DOUBLE COMPLEX for <code>zlarfg</code> On entry, the value <i>alpha</i> .
<i>x</i>	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> DOUBLE COMPLEX for <code>zlarfg</code> Array, size $(1+(n-2)*abs(incx))$. On entry, the vector <i>x</i> .
<i>incx</i>	INTEGER. The increment between elements of <i>x</i> . <i>incx</i> > 0.

Output Parameters

<i>alpha</i>	On exit, it is overwritten with the value <i>beta</i> .
<i>x</i>	On exit, it is overwritten with the vector <i>v</i> .
<i>tau</i>	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> DOUBLE COMPLEX for <code>zlarfg</code> The value <i>tau</i> .

?larfgp

Generates an elementary reflector (Householder matrix) with non-negative beta .

Syntax

```
call slarfgp( n, alpha, x, incx, tau )
call dlarfgp( n, alpha, x, incx, tau )
call clarfgp( n, alpha, x, incx, tau )
call zlarfgp( n, alpha, x, incx, tau )
```

Include Files

- `mkl.fi`

Description

The routine `?larfgp` generates a real/complex elementary reflector *H* of order *n*, such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^T H = I, \quad \text{for real flavors and}$$

$$H^H \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^H H = I, \quad \text{for complex flavors,}$$

where α and β are scalars (with β real and non-negative for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^H \end{bmatrix} \quad \text{for complex flavors,}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that for `c/zlarfgp`, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$ (for complex flavors).

Input Parameters

n	INTEGER. The order of the elementary reflector.
α	REAL for <code>slarfgp</code> DOUBLE PRECISION for <code>dlarfgp</code> COMPLEX for <code>clarfgp</code> DOUBLE COMPLEX for <code>zlarfgp</code> On entry, the value α .
x	REAL for <code>s</code> DOUBLE PRECISION for <code>dlarfgp</code> COMPLEX for <code>clarfgp</code> DOUBLE COMPLEX for <code>zlarfgp</code> Array, DIMENSION $(1+(n-2)*\text{abs}(\text{incx}))$. On entry, the vector x .
incx	INTEGER. The increment between elements of x . $\text{incx} > 0$.

Output Parameters

α	On exit, it is overwritten with the value β .
x	On exit, it is overwritten with the vector v .
τ	REAL for <code>slarfgp</code> DOUBLE PRECISION for <code>dlarfgp</code> COMPLEX for <code>clarfgp</code> DOUBLE COMPLEX for <code>zlarfgp</code>

The value *tau*.

?larft

Forms the triangular factor T of a block reflector $H = I - V^* T^* V^* H$.

Syntax

```
call slarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Include Files

- mkl.fi

Description

The routine ?larft forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1) * H(2) * \dots * H(k)$ and T is upper triangular;

If $direct = 'B'$, $H = H(k) * \dots * H(2) * H(1)$ and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V^* T^* V^T$ (for real flavors) or $H = I - V^* T^* V^H$ (for complex flavors) .

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V^T * T^* V$ (for real flavors) or $H = I - V^H * T^* V$ (for complex flavors).

Input Parameters

The data types are given for the Fortran interface.

<i>direct</i>	CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise.
<i>n</i>	INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.

v	<p>REAL for slarft</p> <p>DOUBLE PRECISION for dlarft</p> <p>COMPLEX for clarft</p> <p>DOUBLE COMPLEX for zlarft</p> <p>Array, DIMENSION</p> <p>(ldv, k) if $storev = 'C'$ or</p> <p>(ldv, n) if $storev = 'R'$.</p> <p>The matrix V.</p>
ldv	<p>INTEGER. The leading dimension of the array v.</p> <p>If $storev = 'C'$, $ldv \geq \max(1, n)$</p> <p>if $storev = 'R'$, $ldv \geq k$.</p>
τ	<p>REAL for slarft</p> <p>DOUBLE PRECISION for dlarft</p> <p>COMPLEX for clarft</p> <p>DOUBLE COMPLEX for zlarft</p> <p>Array, size (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$.</p>
ldt	<p>INTEGER. The leading dimension of the output array t. $ldt \geq k$.</p>

Output Parameters

t	<p>REAL for slarft</p> <p>DOUBLE PRECISION for dlarft</p> <p>COMPLEX for clarft</p> <p>DOUBLE COMPLEX for zlarft</p> <p>Array, size ldt by k. The k-by-k triangular factor T of the block reflector. If $direct = 'F'$, T is upper triangular; if $direct = 'B'$, T is lower triangular. The rest of the array is not used.</p>
v	<p>The matrix V.</p>

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

Input Parameters

The data types are given for the Fortran interface.

<i>side</i>	<p>CHARACTER*1.</p> <p>If <i>side</i> = 'L': form H^*C</p> <p>If <i>side</i> = 'R': form C^*H.</p>
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>v</i>	<p>REAL for slarfx</p> <p>DOUBLE PRECISION for dlarfx</p> <p>COMPLEX for clarfx</p> <p>DOUBLE COMPLEX for zlarfx</p> <p>Array, size</p> <p>(<i>m</i>) if <i>side</i> = 'L' or</p> <p>(<i>n</i>) if <i>side</i> = 'R'.</p> <p>The vector <i>v</i> in the representation of <i>H</i>.</p>
<i>tau</i>	<p>REAL for slarfx</p> <p>DOUBLE PRECISION for dlarfx</p> <p>COMPLEX for clarfx</p> <p>DOUBLE COMPLEX for zlarfx</p> <p>The value <i>tau</i> in the representation of <i>H</i>.</p>
<i>c</i>	<p>REAL for slarfx</p> <p>DOUBLE PRECISION for dlarfx</p> <p>COMPLEX for clarfx</p> <p>DOUBLE COMPLEX for zlarfx</p> <p>Array, size <i>ldc</i> by <i>n</i>. On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.</p>
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $lda \geq (1, m)$.
<i>work</i>	<p>REAL for slarfx</p> <p>DOUBLE PRECISION for dlarfx</p> <p>COMPLEX for clarfx</p> <p>DOUBLE COMPLEX for zlarfx</p> <p>Workspace array, size</p> <p>(<i>n</i>) if <i>side</i> = 'L' or</p> <p>(<i>m</i>) if <i>side</i> = 'R'.</p> <p><i>work</i> is not referenced if <i>H</i> has order < 11.</p>

Output Parameters

c On exit, *c* is overwritten by the matrix H^*C if *side* = 'L', or C^*H if *side* = 'R'.

?large

Pre- and post-multiplies a real general matrix with a random orthogonal matrix.

Syntax

call slarge(*n*, *a*, *lda*, *iseed*, *work*, *info*)

call dlarge(*n*, *a*, *lda*, *iseed*, *work*, *info*)

call clarge(*n*, *a*, *lda*, *iseed*, *work*, *info*)

call zlarge(*n*, *a*, *lda*, *iseed*, *work*, *info*)

Include Files

- mkl.fi

Description

The routine ?large pre- and post-multiplies a general n -by- n matrix A with a random orthogonal or unitary matrix: $A = U^*D^*U^T$.

Input Parameters

n INTEGER. The order of the matrix A . $n \geq 0$

a REAL for slarge,
DOUBLE PRECISION for dlarge,
COMPLEX for clarge,
DOUBLE COMPLEX for zlarge,
Array, size *lda* by n .
On entry, the original n -by- n matrix A .

lda INTEGER. The leading dimension of the array *a*. $lda \geq n$.

iseed INTEGER. Array, size 4.
On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and *iseed*(4) must be odd.

work REAL for slarge,
DOUBLE PRECISION for dlarge,
COMPLEX for clarge,
DOUBLE COMPLEX for zlarge,
Workspace array, size $2*n$.

Output Parameters

<i>a</i>	INTEGER. On exit, <i>A</i> is overwritten by U^*A*U' for some random orthogonal matrix <i>U</i> .
<i>iseed</i>	INTEGER. On exit, the seed is updated.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i> -th parameter had an illegal value.

?largv

Generates a vector of plane rotations with real cosines and real/complex sines.

Syntax

```
call slargv( n, x, incx, y, incy, c, incc )
call dlargv( n, x, incx, y, incy, c, incc )
call clargv( n, x, incx, y, incy, c, incc )
call zlargv( n, x, incx, y, incy, c, incc )
```

Include Files

- mkl.fi

Description

The routine generates a vector of real/complex plane rotations with real cosines, determined by elements of the real/complex vectors *x* and *y*.

For slargv/dlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} a_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

For clargv/zlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} r_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

where $c(i)^2 + \text{abs}(s(i))^2 = 1$ and the following conventions are used (these are the same as in clartg/zlartg but differ from the BLAS Level 1 routine crotg/zrotg):

If $y_i = 0$, then $c(i) = 1$ and $s(i) = 0$;

If $x_i = 0$, then $c(i) = 0$ and $s(i)$ is chosen so that r_i is real.

Input Parameters

n	INTEGER. The number of plane rotations to be generated.
x, y	REAL for slargv DOUBLE PRECISION for dlargv COMPLEX for clargv DOUBLE COMPLEX for zlargv Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. On entry, the vectors x and y .
$incx$	INTEGER. The increment between elements of x . $incx > 0$.
$incy$	INTEGER. The increment between elements of y . $incy > 0$.
$incc$	INTEGER. The increment between elements of the output array c . $incc > 0$.

Output Parameters

x	On exit, $x(i)$ is overwritten by a_i (for real flavors), or by r_i (for complex flavors), for $i = 1, \dots, n$.
y	On exit, the sines $s(i)$ of the plane rotations.
c	REAL for slargv/clargv DOUBLE PRECISION for dlargv/zlargv Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.

?larnd

Returns a random real number from a uniform or normal distribution.

Syntax

```
res = slarnd( idist, iseed )
res = dlarnd( idist, iseed )
res = clarnd( idist, iseed )
res = zlarnd( idist, iseed )
```

Include Files

- mkl.fi

Description

The routine ?larnd returns a random number from a uniform or normal distribution.

Input Parameters

<i>idist</i>	<p>INTEGER. Specifies the distribution of the random numbers. For <code>slarnd</code> and <code>dlarnd</code>:</p> <ul style="list-style-type: none"> = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). <p>For <code>clarnd</code> and <code>zlarnd</code>:</p> <ul style="list-style-type: none"> = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) \leq 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<i>iseed</i>	<p>INTEGER. Array, size 4.</p> <p>On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <code>iseed(4)</code> must be odd.</p>

Output Parameters

<i>iseed</i>	<p>INTEGER.</p> <p>On exit, the seed is updated.</p>
<i>res</i>	<p>REAL for <code>slarnd</code>,</p> <p>DOUBLE PRECISION for <code>dlarnd</code>,</p> <p>COMPLEX for <code>clarnd</code>,</p> <p>DOUBLE COMPLEX for <code>zlarnd</code>,</p> <p>Random number.</p>

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

```
call slarnv( idist, iseed, n, x )
call dlarnv( idist, iseed, n, x )
call clarnd( idist, iseed, n, x )
call zlarnd( idist, iseed, n, x )
```

Include Files

- `mkl.fi`

Description

The routine `?larnv` returns a vector of n random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine `?laruv` to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

The data types are given for the Fortran interface.

<i>idist</i>	<p>INTEGER. Specifies the distribution of the random numbers: for <code>slarnv</code> and <code>dlarnv</code>:</p> <ul style="list-style-type: none"> = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). <p>for <code>clarv</code> and <code>zlarnv</code>:</p> <ul style="list-style-type: none"> = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) < 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<i>iseed</i>	<p>INTEGER. Array, size (4).</p> <p>On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <code>iseed(4)</code> must be odd.</p>
<i>n</i>	<p>INTEGER. The number of random numbers to be generated.</p>

Output Parameters

<i>x</i>	<p>REAL for <code>slarnv</code></p> <p>DOUBLE PRECISION for <code>dlarnv</code></p> <p>COMPLEX for <code>clarv</code></p> <p>DOUBLE COMPLEX for <code>zlarnv</code></p> <p>Array, size (n). The generated random numbers.</p>
<i>iseed</i>	<p>On exit, the seed is updated.</p>

`?laror`

Pre- or post-multiplies an m -by- n matrix by a random orthogonal/unitary matrix.

Syntax

```
call slaror( side, init, m, n, a, lda, iseed, x, info )
call dlaror( side, init, m, n, a, lda, iseed, x, info )
call claror( side, init, m, n, a, lda, iseed, x, info )
```

call `zlaror(side, init, m, n, a, lda, iseed, x, info)`

Include Files

- `mkl.fi`

Description

The routine `?laror` pre- or post-multiplies an m -by- n matrix A by a random orthogonal or unitary matrix U , overwriting A . A may optionally be initialized to the identity matrix before multiplying by U . U is generated using the method of G.W. Stewart (SIAM J. Numer. Anal. 17, 1980, 403-409).

Input Parameters

<i>side</i>	<p>CHARACTER*1. Specifies whether A is multiplied by U on the left or right.</p> <p>for <code>slaror</code> and <code>dlaror</code>:</p> <p>If <i>side</i> = 'L', multiply A on the left (premultiply) by U.</p> <p>If <i>side</i> = 'R', multiply A on the right (postmultiply) by U^T.</p> <p>If <i>side</i> = 'C' or 'T', multiply A on the left by U and the right by U^T.</p> <p>for <code>claror</code> and <code>zlaror</code>:</p> <p>If <i>side</i> = 'L', multiply A on the left (premultiply) by U.</p> <p>If <i>side</i> = 'R', multiply A on the right (postmultiply) by $UC^>$.</p> <p>If <i>side</i> = 'C', multiply A on the left by U and the right by $UC^>$.</p> <p>If <i>side</i> = 'T', multiply A on the left by U and the right by U^T.</p>
<i>init</i>	<p>CHARACTER*1. Specifies whether or not a should be initialized to the identity matrix.</p> <p>If <i>init</i> = 'I', initialize a to (a section of) the identity matrix before applying U.</p> <p>If <i>init</i> = 'N', no initialization. Apply U to the input matrix A.</p> <p><i>init</i> = 'I' generates square or rectangular orthogonal matrices:</p> <p>For $m = n$ and <i>side</i> = 'L' or 'R', the rows and the columns are orthogonal to each other.</p> <p>For rectangular matrices where $m < n$:</p> <ul style="list-style-type: none"> • If <i>side</i> = 'R', <code>?laror</code> produces a dense matrix in which rows are orthogonal and columns are not. • If <i>side</i> = 'L', <code>?laror</code> produces a matrix in which rows are orthogonal, first m columns are orthogonal, and remaining columns are zero. <p>For rectangular matrices where $m > n$:</p> <ul style="list-style-type: none"> • If <i>side</i> = 'L', <code>?laror</code> produces a dense matrix in which columns are orthogonal and rows are not. • If <i>side</i> = 'R', <code>?laror</code> produces a matrix in which columns are orthogonal, first m rows are orthogonal, and remaining rows are zero.
<i>m</i>	INTEGER. The number of rows of A .
<i>n</i>	INTEGER. The number of columns of A .

<i>a</i>	<p>REAL for slaror, DOUBLE PRECISION for dlaror, COMPLEX for claror, DOUBLE COMPLEX for zlaror, Array, size <i>lda</i> by <i>n</i>.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(1, m)$.</p>
<i>iseed</i>	<p>INTEGER. Array, size (4). On entry, specifies the seed of the random number generator. The array elements must be between 0 and 4095; if not they are reduced mod 4096. Also, <i>iseed</i>(4) must be odd.</p>
<i>x</i>	<p>REAL for slaror, DOUBLE PRECISION for dlaror, COMPLEX for claror, DOUBLE COMPLEX for zlaror, Workspace array, size $(3 * \max(m, n))$.</p>

Value of <i>side</i>	Length of workspace
'L'	$2 * m + n$
'R'	$2 * n + m$
'C' or 'T'	$3 * n$

Output Parameters

<i>a</i>	<p>On exit, overwritten by <i>UA</i> (if <i>side</i> = 'L'), by <i>AU</i> (if <i>side</i> = 'R'), by <i>UAU^T</i> (if <i>side</i> = 'C' or 'T').</p>
<i>iseed</i>	<p>The values of <i>iseed</i> are changed on exit, and can be used in the next call to continue the same random number sequence.</p>
<i>info</i>	<p>INTEGER. Array, size (4). For slaror and dlaror: If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = 1, the random numbers generated by ?laror are bad. For claror and zlaror: If <i>info</i> = 0, the execution is successful. If <i>info</i> = -1, <i>side</i> is not 'L', 'R', 'C', or 'T'. If <i>info</i> = -3, if <i>m</i> is negative.</p>

If *info* = -4, if *m* is negative or if *side* is 'C' or 'T' and *n* is not equal to *m* .

If *info* = -6, if *lda* is less than *m* .

?larot

Applies a Givens rotation to two adjacent rows or columns.

Syntax

```
call slarot( lrows, lleft, lright, nl, c, s, a, lda, xleft, xright )
call dlarot( lrows, lleft, lright, nl, c, s, a, lda, xleft, xright )
call clarot( lrows, lleft, lright, nl, c, s, a, lda, xleft, xright )
call zlarot( lrows, lleft, lright, nl, c, s, a, lda, xleft, xright )
```

Include Files

- mkl.fi

Description

The routine ?larot applies a Givens rotation to two adjacent rows or columns, where one element of the first or last column or row is stored in some format other than GE so that elements of the matrix may be used or modified for which no array element is provided.

One example is a symmetric matrix in SB format (bandwidth = 4), for which *uplo* = 'L'. Two adjacent rows will have the format:

```
row j :      C > C > C > C > C > . . . .
row j + 1 :  C > C > C > C > C > . . . .
```

'*' indicates elements for which storage is provided.

'.' indicates elements for which no storage is provided, but are not necessarily zero; their values are determined by symmetry.

' ' indicates elements which are required to be zero, and have no storage provided.

Those columns which have two '*' entries can be handled by srot (for slarot and clarot), or by drot (for dlarot and zlarot).

Those columns which have no '*' entries can be ignored, since as long as the Givens rotations are carefully applied to preserve symmetry, their values are determined.

Those columns which have one '*' have to be handled separately, by using separate variables *p* and *q* :

```
row j :      C > C > C > C > C > p. . . .
row j + 1 :  q C > C > C > C > C > . . . .
```

If element *p* is set correctly, ?larot rotates the column and sets *p* to its new value. The next call to ?larot rotates columns *j* and *j* + 1, and restore symmetry. The element *q* is zero at the beginning, and non-zero after the rotation. Later, rotations would presumably be chosen to zero *q* out.

Typical Calling Sequences: rotating the *i* -th and (*i* + 1) -st rows.

Example

Typical Calling Sequences

These examples rotate the *i* -th and (*i* + 1) -st rows.

General dense matrix:

```
call dlarot ( .TRUE., .FALSE., .FALSE., n, c, s,
a(i,1), lda, dummy, dummy)
```

General banded matrix in GB format:

```
j = max(1, i-kl )
nl = min( n, i+ku+1 ) + 1-j
call dlarot( .TRUE., i-kl.GE.1, i+ku.LT.n, nl, c,s,
a(ku+i+1-j,j), lda-1, xleft, xright )
```

NOTE

$i + 1 - j$ is just $\min(i, kl + 1)$.

Symmetric banded matrix in SY format, bandwidth K, lower triangle only:

```
j = max(1, i-k )
nl = min( k+1, i ) + 1
call dlarot( .TRUE., i-k.GE.1, .TRUE., nl, c,s,
a(i,j), lda, xleft, xright )
```

Same, but upper triangle only:

```
nl = min( k+1, n-i ) + 1
call dlarot( .TRUE., .TRUE., i+k.LT.n, nl, c,s,
a(i,i), lda, xleft, xright )
```

Symmetric banded matrix in SB format, bandwidth K, lower triangle only: [same as for SY, except:]

```
. . . . .
a(i+1-j,j), lda, xleft, xright )
```

NOTE

$i+1-j$ is just $\min(i, k+1)$

Same, but upper triangle only:

```
. . . . .
a(k+1,i), lda-1, xleft, xright )
```

Rotating columns is just the transpose of rotating rows, except for GB and SB: (rotating columns i and $i+1$)
GB:

NOTE

$ku+j+1-i$ is just $\max(1, ku+2-i)$

```
j = max(1, i-ku )
nl = min( n, i+kl+1 ) + 1-j
call dlarot( .TRUE., i-ku.LE.1, i+kl.LT.n, nl, c,s,
a(ku+j+1-i,i), lda-1, xtop, xbottom )
```

SB: (upper triangle)

```
. . . . .
a(k+j+1-i,i), lda-1, xtop, xbottom )
```

SB: (lower triangle) A(1,i), LDA-1, XTOP, XBOTTOM)

```
. . . . .
a(1,i), lda-1, xtop, xbottom )
```

Input Parameters

<i>lrows</i>	<p>LOGICAL.</p> <p>If <i>lrows</i> = .TRUE., ?larot rotates two rows.</p> <p>If <i>lrows</i> = .FALSE., ?larot rotates two columns.</p>
<i>lleft</i>	<p>LOGICAL.</p> <p>If <i>lleft</i> = .TRUE., <i>xleft</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = .FALSE.) or column (if <i>lrows</i>=.TRUE.).</p> <p>If <i>lleft</i> = .FALSE., the corresponding element of <i>a</i> is used.</p>
<i>lright</i>	<p>LOGICAL.</p> <p>If <i>lleft</i> = .TRUE., <i>xright</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = .FALSE.) or column (if <i>lrows</i>=.TRUE.).</p> <p>If <i>lright</i> = .FALSE., the corresponding element of <i>a</i> is used.</p>
<i>nl</i>	<p>INTEGER. The length of the rows (if <i>lrows</i>=.TRUE.) or columns (if <i>lrows</i>=.FALSE.) to be rotated.</p> <p>If <i>xleft</i> or <i>xright</i> are used, the columns or rows they are in should be included in <i>nl</i>, e.g., if <i>lleft</i> = <i>lright</i> = .TRUE., then <i>nl</i> must be at least 2.</p> <p>The number of rows or columns to be rotated exclusive of those involving <i>xleft</i> and/or <i>xright</i> may not be negative, i.e., <i>nl</i> minus how many of <i>lleft</i> and <i>lright</i> are .TRUE. must be at least zero; if not, xerbla is called.</p>
<i>c, s</i>	<p>REAL for slarot,</p> <p>DOUBLE PRECISION for dlarot,</p> <p>COMPLEX for clarot,</p> <p>DOUBLE COMPLEX for zlarot,</p> <p>Specify the Givens rotation to be applied.</p> <p>If <i>lrows</i> = .TRUE., then the matrix</p> $\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$ <p>is applied from the left.</p> <p>If <i>lrows</i> = .FALSE., then the transpose thereof is applied from the right.</p>
<i>a</i>	<p>REAL for slarot,</p> <p>DOUBLE PRECISION for dlarot,</p> <p>COMPLEX for clarot,</p> <p>DOUBLE COMPLEX for zlarot,</p>

The array containing the rows or columns to be rotated. The first element of *a* should be the upper left element to be rotated.

lda

INTEGER. The "effective" leading dimension of *a*.

If *a* contains a matrix stored in GE or SY format, then this is just the leading dimension of *A*.

If *a* contains a matrix stored in band (GB or SB) format, then this should be one less than the leading dimension used in the calling routine. Thus, if *a* is dimensioned *a*(*lda*,*) in ?larot, then *a*(1,*j*) would be the *j*-th element in the first of the two rows to be rotated, and *a*(2,*j*) would be the *j*-th in the second, regardless of how the array may be stored in the calling routine. *a* cannot be dimensioned, because for band format the row number may exceed *lda*, which is not legal FORTRAN.

If *lrows* = .TRUE., then *lda* must be at least 1, otherwise it must be at least *nl* minus the number of .TRUE. values in *xleft* and *xright*.

xleft

REAL for slarot,

DOUBLE PRECISION for dlarot,

COMPLEX for clarot,

DOUBLE COMPLEX for zlarot,

If *lrows* = .TRUE., *xleft* is used and modified instead of *a*(2,1) (if *lrows* = .TRUE.) or *a*(1,2) (if *lrows* = .FALSE.).

xright

REAL for slarot,

DOUBLE PRECISION for dlarot,

COMPLEX for clarot,

DOUBLE COMPLEX for zlarot,

If *lright* = .TRUE., *xright* is used and modified instead of *a*(1,*nl*) (if *lrows* = .TRUE.) or *a*(*nl*,1) (if *lrows* = .FALSE.).

Output Parameters

a

On exit, modified array *A*.

?larra

Computes the splitting points with the specified threshold.

Syntax

```
call slarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
```

```
call dlarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
```

Include Files

- mkl.fi

Description

The routine computes the splitting points with the specified threshold and sets any "small" off-diagonal elements to zero.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix ($n > 1$).
<i>d</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .
<i>e</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). First ($n-1$) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e</i> (<i>n</i>) need not be set.
<i>e2</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). First ($n-1$) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e2</i> (<i>n</i>) need not be set.
<i>spltol</i>	REAL for slarra DOUBLE PRECISION for dlarra The threshold for splitting. Two criteria can be used: <i>spltol</i> < 0 : criterion based on absolute off-diagonal value; <i>spltol</i> > 0 : criterion that preserves relative accuracy.
<i>tnrm</i>	REAL for slarra DOUBLE PRECISION for dlarra The norm of the matrix.

Output Parameters

<i>e</i>	On exit, the entries <i>e</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, are set to zero, the other entries of <i>e</i> are untouched.
<i>e2</i>	On exit, the entries <i>e2</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, are set to zero.
<i>nsplit</i>	INTEGER. The number of blocks the matrix <i>T</i> splits into. $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>).

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, and so on, and the $nsplit$ -th consists of rows/columns $isplit(nspl-1)+1$ through $isplit(nspl)=n$.

info INTEGER.
= 0: successful exit.

?larrb

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

call slarrb(*n*, *d*, *lld*, *ifirst*, *ilast*, *rtol1*, *rtol2*, *offset*, *w*, *wgap*, *werr*, *work*, *iwork*, *pivmin*, *spdiam*, *twist*, *info*)

call dlarrb(*n*, *d*, *lld*, *ifirst*, *ilast*, *rtol1*, *rtol2*, *offset*, *w*, *wgap*, *werr*, *work*, *iwork*, *pivmin*, *spdiam*, *twist*, *info*)

Include Files

- mkl.fi

Description

Given the relatively robust representation (RRR) $L^*D^*L^T$, the routine does "limited" bisection to refine the eigenvalues of $L^*D^*L^T$, w (*ifirst*-offset) through w (*ilast*-offset), to more accuracy. Initial guesses for these eigenvalues are input in w . The corresponding estimate of the error in these guesses and their gaps are input in $werr$ and $wgap$, respectively. During bisection, intervals [*left*, *right*] are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

n INTEGER. The order of the matrix.

d REAL for slarrb
DOUBLE PRECISION for dlarrb
Array, DIMENSION (*n*). The *n* diagonal elements of the diagonal matrix D .

lld REAL for slarrb
DOUBLE PRECISION for dlarrb
Array, DIMENSION (*n*-1).
The *n*-1 elements $L_i^*L_i^*D_i$.

ifirst INTEGER. The index of the first eigenvalue to be computed.

ilast INTEGER. The index of the last eigenvalue to be computed.

rtol1, *rtol2* REAL for slarrb
DOUBLE PRECISION for dlarrb

Tolerance for the convergence of the bisection intervals. An interval $[left, right]$ has converged if $RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*max(|left|, |right|))$, where gap is the (estimated) distance to the nearest eigenvalue.

offset

INTEGER. Offset for the arrays w , $wgap$ and $werr$, that is, the *ifirst-offset* through *ilast-offset* elements of these arrays are to be used.

w

REAL for slarrb

DOUBLE PRECISION for dlarrb

Array, DIMENSION (n). On input, $w(ifirst-offset)$ through $w(ilast-offset)$ are estimates of the eigenvalues of $L*D*L^T$ indexed *ifirst* through *ilast*.

wgap

REAL for slarrb

DOUBLE PRECISION for dlarrb

Array, DIMENSION ($n-1$). The estimated gaps between consecutive eigenvalues of $L*D*L^T$, that is, $wgap(i-offset)$ is the gap between eigenvalues i and $i+1$. Note that if $IFIRST.EQ.ILAST$ then $wgap(ifirst-offset)$ must be set to 0.

werr

REAL for slarrb

DOUBLE PRECISION for dlarrb

Array, DIMENSION (n). On input, $werr(ifirst-offset)$ through $werr(ilast-offset)$ are the errors in the estimates of the corresponding elements in w .

work

REAL for slarrb

DOUBLE PRECISION for dlarrb

Workspace array, DIMENSION ($2*n$).

pivmin

REAL for slarrb

DOUBLE PRECISION for dlarrb

The minimum pivot in the Sturm sequence.

spdiam

REAL for slarrb

DOUBLE PRECISION for dlarrb

The spectral diameter of the matrix.

twist

INTEGER. The twist index for the twisted factorization that is used for the negcount.

$twist = n$: Compute negcount from $L*D*L^T - \lambda_i = L + D + L^T$

$twist = n$: Compute negcount from $L*D*L^T - \lambda_i = U - D - U^T$

$twist = n$: Compute negcount from $L*D*L^T - \lambda_i = N_r^* D_r^* N_r$

iwork

INTEGER.

Workspace array, DIMENSION ($2*n$).

Output Parameters

<i>w</i>	On output, the estimates of the eigenvalues are "refined".
<i>wgap</i>	On output, the gaps are refined.
<i>werr</i>	On output, "refined" errors in the estimates of <i>w</i> .
<i>info</i>	INTEGER. Error flag.

?larrc

Computes the number of eigenvalues of the symmetric tridiagonal matrix.

Syntax

```
call slarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
call dlarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
```

Include Files

- mkl.fi

Description

The routine finds the number of eigenvalues of the symmetric tridiagonal matrix T or of its factorization L^*D*L^T in the specified interval.

Input Parameters

<i>jobt</i>	CHARACTER*1. = 'T': computes Sturm count for matrix T . = 'L': computes Sturm count for matrix L^*D*L^T .
<i>n</i>	INTEGER. The order of the matrix. ($n > 1$).
<i>vl,vu</i>	REAL for slarrc DOUBLE PRECISION for dlarrc The lower and upper bounds for the eigenvalues.
<i>d</i>	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If <i>jobt</i> = 'T': contains the n diagonal elements of the tridiagonal matrix T . If <i>jobt</i> = 'L': contains the n diagonal elements of the diagonal matrix D .
<i>e</i>	REAL for slarrc DOUBLE PRECISION for dlarrc

Array, DIMENSION (n).

If $jobt = 'T'$: contains the $(n-1)$ offdiagonal elements of the matrix T .

If $jobt = 'L'$: contains the $(n-1)$ offdiagonal elements of the matrix L .

pivmin

REAL for slarrc

DOUBLE PRECISION for dlarrc

The minimum pivot in the Sturm sequence for the matrix T .

Output Parameters

eigcnt

INTEGER.

The number of eigenvalues of the symmetric tridiagonal matrix T that are in the half-open interval $(vl, vu]$.

lcnt,rcnt

INTEGER.

The left and right negcounts of the interval.

info

INTEGER.

Now it is not used and always is set to 0.

?larrd

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

call slarrd(range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info)

call dlarrd(range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin, nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info)

Include Files

- mkl.fi

Description

The routine computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from ?stemr. The user may ask for all eigenvalues, all eigenvalues in the half-open interval $(vl, vu]$, or the il -th through iu -th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. (For more details see [Kahan66].

Input Parameters

range

CHARACTER.

= 'A': ("All") all eigenvalues will be found.

	<p>= 'V': ("Value") all eigenvalues in the half-open interval (vl, vu] will be found.</p> <p>= 'I': ("Index") the il-th through iu-th eigenvalues will be found.</p>
<i>order</i>	<p>CHARACTER.</p> <p>= 'B': ("By block") the eigenvalues will be grouped by split-off block (see <i>iblock</i>, <i>isplit</i> below) and ordered from smallest to largest within the block.</p> <p>= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.</p>
<i>n</i>	INTEGER. The order of the tridiagonal matrix T ($n \geq 1$).
<i>vl,vu</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>If <i>range</i> = 'V': the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to vl, or greater than vu, will not be returned. $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I': not referenced.</p>
<i>il,iu</i>	<p>INTEGER.</p> <p>If <i>range</i> = 'I': the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n=0$.</p> <p>If <i>range</i> = 'A' or 'V': not referenced.</p>
<i>gers</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>Array, DIMENSION ($2*n$).</p> <p>The n Gerschgorin intervals (the i-th Gerschgorin interval is ($gers(2*i-1)$, $gers(2*i)$)).</p>
<i>reltol</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i>.</p>
<i>d</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>Array, DIMENSION (n).</p> <p>Contains n diagonal elements of the tridiagonal matrix T.</p>
<i>e</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p>

	<p>Array, DIMENSION ($n-1$).</p> <p>Contains ($n-1$) off-diagonal elements of the tridiagonal matrix T.</p>
<i>e2</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>Array, DIMENSION ($n-1$).</p> <p>Contains ($n-1$) squared off-diagonal elements of the tridiagonal matrix T.</p>
<i>pivmin</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>The minimum pivot in the Sturm sequence for the matrix T.</p>
<i>nsplit</i>	<p>INTEGER.</p> <p>The number of diagonal blocks the matrix T. $1 \leq nsplit \leq n$</p>
<i>isplit</i>	<p>INTEGER.</p> <p>Arrays, DIMENSION (n).</p> <p>The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i>(1), the second of rows/columns <i>isplit</i>(1)+1 through <i>isplit</i>(2), and so on, and the <i>nsplit</i>-th consists of rows/columns <i>isplit</i>(<i>nsplit</i>-1)+1 through <i>isplit</i>(<i>nsplit</i>)=n.</p> <p>(Only the first <i>nsplit</i> elements actually is used, but since the user cannot know a priori value of <i>nsplit</i>, n words must be reserved for <i>isplit</i>.)</p>

<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION ($4*n$).</p>

Output Parameters

<i>m</i>	<p>INTEGER.</p> <p>The actual number of eigenvalues found. $0 \leq m \leq n$. (See also the description of <i>info</i>=2, 3.)</p>
<i>w</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>Array, DIMENSION (n).</p> <p>The first m elements of w contain the eigenvalue approximations. ?laprd computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue j. The eigenvalue approximation is given as the interval midpoint $w(j) = (a_j + b_j) / 2$. The corresponding error is bounded by $werr(j) = \text{abs}(a_j - b_j) / 2$.</p>

<i>werr</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The error bound on the corresponding eigenvalue approximation in <i>w</i>.</p>
<i>wl, wu</i>	<p>REAL for slarrd</p> <p>DOUBLE PRECISION for dlarrd</p> <p>The interval (<i>wl</i>, <i>wu</i>] contains all the wanted eigenvalues.</p> <p>If <i>range</i> = 'V': then <i>wl</i>=<i>vl</i> and <i>wu</i>=<i>vu</i>.</p> <p>If <i>range</i> = 'A': then <i>wl</i> and <i>wu</i> are the global Gerschgorin bounds on the spectrum.</p> <p>If <i>range</i> = 'I': then <i>wl</i> and <i>wu</i> are computed by ?laebz from the index range specified.</p>
<i>iblock</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>At each row/column <i>j</i> where <i>e(j)</i> is zero or small, the matrix <i>T</i> is considered to split into a block diagonal matrix.</p> <p>If <i>info</i> = 0, then <i>iblock(i)</i> specifies to which block (from 1 to the number of blocks) the eigenvalue <i>w(i)</i> belongs. (The routine may use the remaining <i>n-m</i> elements as workspace.)</p>
<i>indexw</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The indices of the eigenvalues within each block (submatrix); for example, <i>indexw(i)</i>= <i>j</i> and <i>iblock(i)</i>=<i>k</i> imply that the <i>i</i>-th eigenvalue <i>w(i)</i> is the <i>j</i>-th eigenvalue in block <i>k</i>.</p>
<i>info</i>	<p>INTEGER.</p> <p>= 0: successful exit.</p> <p>< 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument has an illegal value</p> <p>> 0: some or all of the eigenvalues fail to converge or are not computed:</p> <p>=1 or 3: bisection fail to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.</p> <p>=2 or 3: <i>range</i>='I' only: not all of the eigenvalues <i>il:iu</i> are found.</p> <p>=4: <i>range</i>='I', and the Gerschgorin interval initially used is too small. No eigenvalues are computed.</p>

?larre

Given the tridiagonal matrix *T*, sets small off-diagonal elements to zero and for each unreduced block *T_i*, finds base representations and eigenvalues.

Syntax

```
call slarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

```
call dlarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit, isplit,
m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

Include Files

- mkl.fi

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , the routine sets any "small" off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block spectrum
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then used by `?stemr` to compute the eigenvectors of a symmetric tridiagonal matrix. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the `dqds` algorithm (subroutine `?lasq2`) to compute all and discard any unwanted one. As an added benefit, `?larre` also outputs the n Gerschgorin intervals for the matrices $L_i D_i L_i^T$.

Input Parameters

<i>range</i>	<p>CHARACTER.</p> <p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>= 'I': ("Index") the il-th through iu-th eigenvalues of the entire matrix will be found.</p>
<i>n</i>	<p>INTEGER. The order of the matrix. $n > 0$.</p>
<i>vl, vu</i>	<p>REAL for <code>slarre</code></p> <p>DOUBLE PRECISION for <code>dlarre</code></p> <p>If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, are not returned. $vl < vu$.</p>
<i>il, iu</i>	<p>INTEGER.</p> <p>If <i>range</i>='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$.</p>
<i>d</i>	<p>REAL for <code>slarre</code></p> <p>DOUBLE PRECISION for <code>dlarre</code></p> <p>Array, DIMENSION (n).</p> <p>The n diagonal elements of the diagonal matrices T.</p>
<i>e</i>	<p>REAL for <code>slarre</code></p>

	DOUBLE PRECISION for dlarre
	Array, DIMENSION (n). The first ($n-1$) entries contain the subdiagonal elements of the tridiagonal matrix T ; $e(n)$ need not be set.
$e2$	REAL for slarre
	DOUBLE PRECISION for dlarre
	Array, DIMENSION (n). The first ($n-1$) entries contain the squares of the subdiagonal elements of the tridiagonal matrix T ; $e2(n)$ need not be set.
$rtol1, rtol2$	REAL for slarre
	DOUBLE PRECISION for dlarre
	Parameters for bisection. An interval $[LEFT, RIGHT]$ has converged if $RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*max(LEFT , RIGHT))$.
$spltol$	REAL for slarre
	DOUBLE PRECISION for dlarre
	The threshold for splitting.
$work$	REAL for slarre
	DOUBLE PRECISION for dlarre
	Workspace array, DIMENSION ($6*n$).
$iwork$	INTEGER.
	Workspace array, DIMENSION ($5*n$).

Output Parameters

vl, vu	On exit, if $range='I'$ or $'A'$, contain the bounds on the desired part of the spectrum.
d	On exit, the n diagonal elements of the diagonal matrices D_i .
e	On exit, the subdiagonal elements of the unit bidiagonal matrices L_i . The entries $e(isplit(i))$, $1 \leq i \leq nsplit$, contain the base points σ_i on output.
$e2$	On exit, the entries $e2(isplit(i))$, $1 \leq i \leq nsplit$, have been set to zero.
$nsplit$	INTEGER. The number of blocks T splits into. $1 \leq nsplit \leq n$.
$isplit$	INTEGER. Array, DIMENSION (n). The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, etc., and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.
m	INTEGER. The total number of eigenvalues (of all the $L_i*D_i*L_i^T$) found.
w	REAL for slarre
	DOUBLE PRECISION for dlarre

Array, DIMENSION (n). The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i * D_i * L_i^T$, are sorted in ascending order. The routine may use the remaining $n-m$ elements as workspace.

werr

REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION (n). The error bound on the corresponding eigenvalue in w .

wgap

REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION (n). The separation from the right neighbor eigenvalue in w . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block the left gap is stored.

iblock

INTEGER. Array, DIMENSION (n).

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $=2$ if $w(i)$ belongs to the second block, etc.

indexw

INTEGER. Array, DIMENSION (n).

The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.

gers

REAL for slarre

DOUBLE PRECISION for dlarre

Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$).

pivmin

REAL for slarre

DOUBLE PRECISION for dlarre

The minimum pivot in the Sturm sequence for T .

info

INTEGER.

If $info = 0$: successful exit

If $info > 0$: A problem occurred in ?larre. If $info = 5$, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If $info < 0$: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter *info* for further information is required.

- If $info = -1$, there is a problem in ?larrd
- If $info = -2$, no base representation could be found in *maxtry* iterations. Increasing *maxtry* and recompilation might be a remedy.
- If $info = -3$, there is a problem in ?larrb when computing the refined root representation for ?lasq2.

- If *info* = -4, there is a problem in ?larrb when performing bisection on the desired part of the spectrum.
- If *info* = -5, there is a problem in ?lasq2.
- If *info* = -6, there is a problem in ?lasq2.

pivmin, sigma, dplus, lplus, work, info )
```

Include Files

- mkl.fi

Description

Given the initial representation $L*D*L^T$ and its cluster of close eigenvalues (in a relative measure), $w(clstrt)$, $w(clstrt+1)$, ... $w(clend)$, the routine ?larrf finds a new relatively robust representation

$$L*D*L^T - \sigma_i * I = L(+) * D(+) * L(+)^T$$

such that at least one of the eigenvalues of $L(+) * D(+) * L(+)^T$ is relatively isolated.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix (subblock, if the matrix is splitted).
<i>d</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1).

The $n-1$ elements $L_i * D_i$.

clstrt INTEGER. The index of the first eigenvalue in the cluster.

clend INTEGER. The index of the last eigenvalue in the cluster.

w REAL for slarrf

DOUBLE PRECISION for dlarrf

Array, $\text{DIMENSION} \geq (\text{clend} - \text{clstrt} + 1)$. The eigenvalue approximations of $L * D * L^T$ in ascending order. $w(\text{clstrt})$ through $w(\text{clend})$ form the cluster of relatively close eigenvalues.

wgap REAL for slarrf

DOUBLE PRECISION for dlarrf

Array, $\text{DIMENSION} \geq (\text{clend} - \text{clstrt} + 1)$. The separation from the right neighbor eigenvalue in w .

werr REAL for slarrf

DOUBLE PRECISION for dlarrf

Array, $\text{DIMENSION} \geq (\text{clend} - \text{clstrt} + 1)$. On input, *werr* contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in w .

spdiam REAL for slarrf

DOUBLE PRECISION for dlarrf

Estimate of the spectral diameter obtained from the Gerschgorin intervals.

clgapl, clgapr REAL for slarrf

DOUBLE PRECISION for dlarrf

Absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.

pivmin REAL for slarrf

DOUBLE PRECISION for dlarrf

The minimum pivot allowed in the Sturm sequence.

work REAL for slarrf

DOUBLE PRECISION for dlarrf

Workspace array, $\text{DIMENSION} (2*n)$.

Output Parameters

wgap On output, the gaps are refined.

sigma REAL for slarrf

DOUBLE PRECISION for dlarrf

The shift used to form $L(+) * D * (+) * L(+)^T$.

dplus REAL for slarrf
DOUBLE PRECISION for dlarrf
Array, DIMENSION (*n*). The *n* diagonal elements of the diagonal matrix $D(+)$.

lplus REAL for slarrf
DOUBLE PRECISION for dlarrf
Array, DIMENSION (*n*). The first (*n*-1) elements of *lplus* contain the subdiagonal elements of the unit bidiagonal matrix $L(+)$.

?larrj

Performs refinement of the initial estimates of the eigenvalues of the matrix T .

Syntax

```
call slarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork, pivmin,
            spdiam, info )
```

```
call dlarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork, pivmin,
            spdiam, info )
```

Include Files

- mkl.fi

Description

Given the initial eigenvalue approximations of T , this routine does bisection to refine the eigenvalues of T , $w(\text{ifirst}-\text{offset})$ through $w(\text{ilast}-\text{offset})$, to more accuracy. Initial guesses for these eigenvalues are input in w , the corresponding estimate of the error in these guesses in $werr$. During bisection, intervals $[a,b]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

n INTEGER. The order of the matrix T .

d REAL for slarrj
DOUBLE PRECISION for dlarrj
Array, DIMENSION (*n*).
Contains *n* diagonal elements of the matrix T .

e2 REAL for slarrj
DOUBLE PRECISION for dlarrj
Array, DIMENSION (*n*-1).
Contains (*n*-1) squared sub-diagonal elements of the T .

ifirst INTEGER.
The index of the first eigenvalue to be computed.

<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rtol</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Tolerance for the convergence of the bisection intervals. An interval $[a,b]$ is considered to be converged if $(b-a) \leq rtol * \max(a , b)$.
<i>offset</i>	INTEGER. Offset for the arrays <i>w</i> and <i>werr</i> , that is the <i>ifirst-offset</i> through <i>ilast-offset</i> elements of these arrays are to be used.
<i>w</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (<i>n</i>). On input, <i>w(ifirst-offset)</i> through <i>w(ilast-offset)</i> are estimates of the eigenvalues of L^*D*L^T indexed <i>ifirst</i> through <i>ilast</i> .
<i>werr</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (<i>n</i>). On input, <i>werr(ifirst-offset)</i> through <i>werr(ilast-offset)</i> are the errors in the estimates of the corresponding elements in <i>w</i> .
<i>work</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Workspace array, DIMENSION ($2*n$).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION ($2*n$).
<i>pivmin</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The minimum pivot in the Sturm sequence for the matrix <i>T</i> .
<i>spdiam</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The spectral diameter of the matrix <i>T</i> .

Output Parameters

<i>w</i>	On exit, contains the refined estimates of the eigenvalues.
<i>werr</i>	On exit, contains the refined errors in the estimates of the corresponding elements in <i>w</i> .
<i>info</i>	INTEGER.

Now it is not used and always is set to 0.

?larrk

Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.

Syntax

```
call slarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
call dlarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
```

Include Files

- mkl.fi

Description

The routine computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from ?stemr.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. For more details see [[Kahan66](#)].

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T . ($n \geq 1$).
<i>iw</i>	INTEGER. The index of the eigenvalue to be returned.
<i>gl, gu</i>	REAL for slarrk DOUBLE PRECISION for dlarrk An upper and a lower bound on the eigenvalue.
<i>d</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
<i>e2</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Array, DIMENSION ($n-1$). Contains ($n-1$) squared off-diagonal elements of the T .
<i>pivmin</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum pivot in the Sturm sequence for the matrix T .
<i>reltol</i>	REAL for slarrk

DOUBLE PRECISION for dlarrk

The minimum relative width of an interval. When an interval is narrower than *reltol* times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least *radix*machine epsilon*.

Output Parameters

w

REAL for slarrk

DOUBLE PRECISION for dlarrk

Contains the eigenvalue approximation.

werr

REAL for slarrk

DOUBLE PRECISION for dlarrk

Contains the error bound on the corresponding eigenvalue approximation in *w*.

info

INTEGER.

= 0: Eigenvalue converges

= -1: Eigenvalue does not converge

?larr

Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

call slarr(*n*, *d*, *e*, *info*)

call dlarr(*n*, *d*, *e*, *info*)

Include Files

- mkl.fi

Description

The routine performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Input Parameters

n

INTEGER. The order of the matrix T . ($n > 0$).

d

REAL for slarr

DOUBLE PRECISION for dlarr

Array, DIMENSION (n).

Contains n diagonal elements of the matrix T .

`e` REAL for slarrv
 DOUBLE PRECISION for dlarrv
 Array, DIMENSION (n).
 The first $(n-1)$ entries contain sub-diagonal elements of the tridiagonal matrix T ; $e(n)$ is set to 0.

Output Parameters

`info` INTEGER.
 = 0: the matrix warrants computations preserving relative accuracy (default value).
 = -1: the matrix warrants computations guaranteeing only absolute accuracy.

?larrv

*Computes the eigenvectors of the tridiagonal matrix $T = L*D*L^T$ given L , D and the eigenvalues of $L*D*L^T$.*

Syntax

```
call slarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call dlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call clarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
call zlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1, rtol2, w,
werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info )
```

Include Files

- mkl.fi

Description

The routine ?larrv computes the eigenvectors of the tridiagonal matrix $T = L*D*L^T$ given L , D and approximations to the eigenvalues of $L*D*L^T$.

The input eigenvalues should have been computed by slarre for real flavors (slarrv/clarrv) and by dlarre for double precision flavors (dlarrv/zlarrv).

Input Parameters

`n` INTEGER. The order of the matrix. $n \geq 0$.
`vl, vu` REAL for slarrv/clarrv
 DOUBLE PRECISION for dlarrv/zlarrv

Lower and upper bounds respectively of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range.

d

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (*n*). On entry, the *n* diagonal elements of the diagonal matrix *D*.

l

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (*n*).

On entry, the (*n*-1) subdiagonal elements of the unit bidiagonal matrix *L* are contained in elements 1 to *n*-1 of *L* if the matrix is not splitted. At the end of each block the corresponding shift is stored as given by *slarre* for real flavors and by *dlarre* for double precision flavors.

pivmin

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

The minimum pivot allowed in the Sturm sequence.

isplit

INTEGER. Array, DIMENSION (*n*).

The splitting points, at which *T* breaks up into blocks. The first block consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), etc.

m

INTEGER. The total number of eigenvalues found.

$0 \leq m \leq n$. If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu* - *il* + 1.

dol, dou

INTEGER.

If you want to compute only selected eigenvectors from all the eigenvalues supplied, specify an index range *dol:dou*. Or else apply the setting *dol*=1, *dou*=*m*. Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*.

If you want to compute only selected eigenpairs, then the columns *dol*-1 to *dou*+1 of the eigenvector space *Z* contain the computed eigenvectors. All other columns of *Z* are set to zero.

minrgp, rtol1, rtol2

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Parameters for bisection. An interval [LEFT,RIGHT] has converged if $\text{RIGHT} - \text{LEFT} < \text{MAX}(\text{rtol1} * \text{gap}, \text{rtol2} * \max(|\text{LEFT}|, |\text{RIGHT}|))$.

w

REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (n). The first m elements of w contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (the output array w from `?larre` is expected here). These eigenvalues are set with respect to the shift of the corresponding root representation for their block.

werr REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (n). The first m elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in w .

wgap REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION (n). The separation from the right neighbor eigenvalue in w .

iblock INTEGER. Array, DIMENSION (n).

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $=2$ if $w(i)$ belongs to the second block, etc.

indexw INTEGER. Array, DIMENSION (n).

The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.

gers REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$). The Gerschgorin intervals should be computed from the original unshifted matrix.

ldz INTEGER. The leading dimension of the output array Z . $ldz \geq 1$, and if $jobz = 'V'$, $ldz \geq \max(1, n)$.

work REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv

Workspace array, DIMENSION ($12*n$).

iwork INTEGER.

Workspace array, DIMENSION ($7*n$).

Output Parameters

d On exit, d may be overwritten.

l On exit, l is overwritten.

<i>w</i>	On exit, <i>w</i> holds the eigenvalues of the unshifted matrix.
<i>werr</i>	On exit, <i>werr</i> contains refined values of its input approximations.
<i>wgap</i>	On exit, <i>wgap</i> contains refined values of its input approximations. Very small gaps are changed.
<i>z</i>	<p>REAL for slarrv</p> <p>DOUBLE PRECISION for dlarrv</p> <p>COMPLEX for clarrv</p> <p>DOUBLE COMPLEX for zlarrv</p> <p>Array, DIMENSION (<i>ldz</i>, max(1,<i>m</i>)).</p> <p>If <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the input eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>).</p>

NOTE

The user must ensure that at least max(1,*m*) columns are supplied in the array *z*.

<i>isuppz</i>	<p>INTEGER .</p> <p>Array, DIMENSION (2*max(1,<i>m</i>)). The support of the eigenvectors in <i>z</i>, that is, the indices indicating the nonzero elements in <i>z</i>. The <i>i</i>-th eigenvector is nonzero only in elements <i>isuppz</i>(2<i>i</i>-1) through <i>isuppz</i>(2<i>i</i>).</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0: successful exit</p> <p>If <i>info</i> > 0: A problem occurred in ?larrv. If <i>info</i> = 5, the Rayleigh Quotient Iteration failed to converge to full accuracy.</p> <p>If <i>info</i> < 0: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter <i>info</i> for further information is required.</p> <ul style="list-style-type: none"> • If <i>info</i> = -1, there is a problem in ?larrb when refining a child eigenvalue; • If <i>info</i> = -2, there is a problem in ?larrf when computing the relatively robust representation (RRR) of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter <i>minrgp</i> smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/<i>minrgp</i>, you should be aware that you might be trading in precision when you decrease <i>minrgp</i>. • If <i>info</i> = -3, there is a problem in ?larrb when refining a single eigenvalue after the Rayleigh correction was rejected.

?lartg

Generates a plane rotation with real cosine and real/complex sine.

Syntax

```
call slartg( f, g, cs, sn, r )
```

```
call dlartg( f, g, cs, sn, r )
```

```
call clartg( f, g, cs, sn, r )
```

```
call zlartg( f, g, cs, sn, r )
```

Include Files

- mkl.fi

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -\text{conjg}(sn) & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + |sn|^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine [?rotg](#), except for the following differences.

For `slartg/dlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$ and $g \neq 0$, then $cs=0$ and $sn=1$ without doing any floating point operations (saves work in `?bdsqr` when there are zeros on the diagonal);

If f exceeds g in magnitude, cs will be positive.

For `clartg/zlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$, then $cs=0$ and sn is chosen so that r is real.

Input Parameters

f, g

REAL for `slartg`

DOUBLE PRECISION for `dlartg`

COMPLEX for `clartg`

DOUBLE COMPLEX for `zlartg`

The first and second component of vector to be rotated.

Output Parameters

<i>cs</i>	<p>REAL for slartg/clartg</p> <p>DOUBLE PRECISION for dlartg/zlartg</p> <p>The cosine of the rotation.</p>
<i>sn</i>	<p>REAL for slartg</p> <p>DOUBLE PRECISION for dlartg</p> <p>COMPLEX for clartg</p> <p>DOUBLE COMPLEX for zlartg</p> <p>The sine of the rotation.</p>
<i>r</i>	<p>REAL for slartg</p> <p>DOUBLE PRECISION for dlartg</p> <p>COMPLEX for clartg</p> <p>DOUBLE COMPLEX for zlartg</p> <p>The nonzero component of the rotated vector.</p>

?lartgp

Generates a plane rotation.

Syntax

```
call slartgp( f, g, cs, sn, r )
call dlartgp( f, g, cs, sn, r )
call lartgp( f, g, cs, sn, r )
```

Include Files

- mkl.fi

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + sn^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine ?rotg, except for the following differences:

- *f* and *g* are unchanged on return.
- If *g*=0, then *cs*=(+/-)1 and *sn*=0.
- If *f*=0 and *g*≠ 0, then *cs*=0 and *sn*=(+/-)1.

The sign is chosen so that $r \geq 0$.

Input Parameters

The data types are given for the Fortran interface.

f, g	REAL for slartgp DOUBLE PRECISION for dlartgp
--------	--

The first and second component of the vector to be rotated.

Output Parameters

cs	REAL for slartgp DOUBLE PRECISION for dlartgp
------	--

The cosine of the rotation.

sn	REAL for slartgp DOUBLE PRECISION for dlartgp
------	--

The sine of the rotation.

r	REAL for slartgp DOUBLE PRECISION for dlartgp
-----	--

The nonzero component of the rotated vector.

$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -1$, f is NaN. If $info = -2$, g is NaN.
--------	---

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `?lartgp` interface are as follows:

f	Holds the first component of the vector to be rotated.
g	Holds the second component of the vector to be rotated.
cs	Holds the cosine of the rotation.
sn	Holds the sine of the rotation.
r	Holds the nonzero component of the rotated vector.

zlartgs

Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Syntax

```
call slartgs( x, y, sigma, cs, sn )
call dlartgs( x, y, sigma, cs, sn )
call lartgs( x,y,sigma,cs,sn )
```

Include Files

- mkl.fi

Description

The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. x and y are the top-row entries, and σ is the shift. The computed cs and sn define a plane rotation that satisfies the following:

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} x^2 - \sigma \\ x * y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

with r nonnegative.

If $x^2 - \sigma$ and $x * y$ are 0, the rotation is by $\pi/2$

Input Parameters

The data types are given for the Fortran interface.

x, y	REAL for slartgs DOUBLE PRECISION for dlartgs The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively.
σ	REAL for slartgs DOUBLE PRECISION for dlartgs Shift

Output Parameters

cs	REAL for slartgs DOUBLE PRECISION for dlartgs The cosine of the rotation.
sn	REAL for slartgs DOUBLE PRECISION for dlartgs The sine of the rotation.

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `?lartgs` interface are as follows:

<code>x</code>	Holds the (1,1) entry of an upper diagonal matrix.
<code>y</code>	Holds the (1,2) entry of an upper diagonal matrix.
<code>sigma</code>	Holds the shift.
<code>cs</code>	Holds the cosine of the rotation.
<code>sn</code>	Holds the sine of the rotation.

?lartv

Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.

Syntax

```
call slartv( n, x, incx, y, incy, c, s, incc )
call dlartv( n, x, incx, y, incy, c, s, incc )
call clartv( n, x, incx, y, incy, c, s, incc )
call zlartv( n, x, incx, y, incy, c, s, incc )
```

Include Files

- `mkl.fi`

Description

The routine applies a vector of real/complex plane rotations with real cosines to elements of the real/complex vectors `x` and `y`. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} := \begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

Input Parameters

<code>n</code>	INTEGER. The number of plane rotations to be applied.
<code>x, y</code>	REAL for <code>slartv</code> DOUBLE PRECISION for <code>dlartv</code>

	COMPLEX for clartv
	DOUBLE COMPLEX for zlartv
	Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. The input vectors x and y .
<i>incx</i>	INTEGER. The increment between elements of x . $incx > 0$.
<i>incy</i>	INTEGER. The increment between elements of y . $incy > 0$.
<i>c</i>	REAL for slartv/clartv DOUBLE PRECISION for dlartv/zlartv Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.
<i>s</i>	REAL for slartv DOUBLE PRECISION for dlartv COMPLEX for clartv DOUBLE COMPLEX for zlartv Array, DIMENSION $(1+(n-1)*incc)$. The sines of the plane rotations.
<i>incc</i>	INTEGER. The increment between elements of c and s . $incc > 0$.

Output Parameters

x, y	The rotated vectors x and y .
--------	-----------------------------------

?laruv

Returns a vector of n random real numbers from a uniform distribution.

Syntax

```
call slaruv( iseed, n, x )
call dlartv( iseed, n, x )
```

Include Files

- mkl.fi

Description

The routine ?laruv returns a vector of n random real numbers from a uniform (0,1) distribution ($n \leq 128$). This is an auxiliary routine called by ?larnv.

Input Parameters

<i>iseed</i>	INTEGER. Array, DIMENSION (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
<i>n</i>	INTEGER. The number of random numbers to be generated. $n \leq 128$.

Output Parameters

<i>x</i>	REAL for slaruv DOUBLE PRECISION for dlaruv Array, DIMENSION (<i>n</i>). The generated random numbers.
<i>seed</i>	On exit, the seed is updated.

?larz

Applies an elementary reflector (as returned by ?tzzrzf) to a general matrix.

Syntax

```
call slarz( side, m, n, l, v, incv, tau, c, ldc, work )
call dlarz( side, m, n, l, v, incv, tau, c, ldc, work )
call clarz( side, m, n, l, v, incv, tau, c, ldc, work )
call zlarz( side, m, n, l, v, incv, tau, c, ldc, work )
```

Include Files

- mkl.fi

Description

The routine ?larz applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the forms

$H = I - \tau u v^T$ for real flavors and $H = I - \tau u v^H$ for complex flavors,

where τu is a real/complex scalar and v is a real/complex vector, respectively.

If $\tau u = 0$, then H is taken to be the unit matrix.

For complex flavors, to apply H^H (the conjugate transpose of H), supply $\text{conj}(\tau u)$ instead of τu .

H is a product of k elementary reflectors as returned by ?tzzrzf.

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H
<i>m</i>	INTEGER. The number of rows of the matrix C .

<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>l</i>	<p>INTEGER. The number of entries of the vector <i>v</i> containing the meaningful part of the Householder vectors.</p> <p>If <i>side</i> = 'L', $m \geq l \geq 0$,</p> <p>if <i>side</i> = 'R', $n \geq l \geq 0$.</p>
<i>v</i>	<p>REAL for slarz</p> <p>DOUBLE PRECISION for dlarz</p> <p>COMPLEX for clarz</p> <p>DOUBLE COMPLEX for zlarz</p> <p>Array, DIMENSION (1+(<i>l</i>-1)*abs(<i>incv</i>)).</p> <p>The vector <i>v</i> in the representation of <i>H</i> as returned by ?tzzrf.</p> <p><i>v</i> is not used if <i>tau</i> = 0.</p>
<i>incv</i>	<p>INTEGER. The increment between elements of <i>v</i>.</p> <p><i>incv</i> ≠ 0.</p>
<i>tau</i>	<p>REAL for slarz</p> <p>DOUBLE PRECISION for dlarz</p> <p>COMPLEX for clarz</p> <p>DOUBLE COMPLEX for zlarz</p> <p>The value <i>tau</i> in the representation of <i>H</i>.</p>
<i>c</i>	<p>REAL for slarz</p> <p>DOUBLE PRECISION for dlarz</p> <p>COMPLEX for clarz</p> <p>DOUBLE COMPLEX for zlarz</p> <p>Array, DIMENSION (<i>ldc</i>,<i>n</i>).</p> <p>On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.</p>
<i>ldc</i>	<p>INTEGER. The leading dimension of the array <i>c</i>.</p> <p>$ldc \geq \max(1, m)$.</p>
<i>work</i>	<p>REAL for slarz</p> <p>DOUBLE PRECISION for dlarz</p> <p>COMPLEX for clarz</p> <p>DOUBLE COMPLEX for zlarz</p> <p>Workspace array, DIMENSION</p> <p>(<i>n</i>) if <i>side</i> = 'L' or</p> <p>(<i>m</i>) if <i>side</i> = 'R'.</p>

Output Parameters

c On exit, *C* is overwritten by the matrix H^*C if *side* = 'L', or C^*H if *side* = 'R'.

?larzb

Applies a block reflector or its transpose/conjugate-transpose to a general matrix.

Syntax

```
call slarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

```
call dlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

```
call clarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

```
call zlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc, work,
ldwork )
```

Include Files

- mkl.fi

Description

The routine applies a real/complex block reflector H or its transpose H^T (or the conjugate transpose H^H for complex flavors) to a real/complex distributed m -by- n matrix C from the left or the right. Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

side CHARACTER*1.
 If *side* = 'L': apply H or H^T/H^H from the left
 If *side* = 'R': apply H or H^T/H^H from the right

trans CHARACTER*1.
 If *trans* = 'N': apply H (No transpose)
 If *trans*='C': apply H^H (conjugate transpose)
 If *trans*='T': apply H^T (transpose transpose)

direct CHARACTER*1.
 Indicates how H is formed from a product of elementary reflectors
 = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward, not supported)
 = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)

storev CHARACTER*1.
 Indicates how the vectors which define the elementary reflectors are stored:

= 'C': Column-wise (not supported)

= 'R': Row-wise.

<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. The order of the matrix <i>T</i> (equal to the number of elementary reflectors whose product defines the block reflector).
<i>l</i>	<p>INTEGER. The number of columns of the matrix <i>V</i> containing the meaningful part of the Householder reflectors.</p> <p>If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$.</p>
<i>v</i>	<p>REAL for slarzb</p> <p>DOUBLE PRECISION for dlarzb</p> <p>COMPLEX for clarzb</p> <p>DOUBLE COMPLEX for zlarzb</p> <p>Array, DIMENSION (<i>ldv</i>, <i>nv</i>).</p> <p>If <i>storev</i> = 'C', <i>nv</i> = <i>k</i>;</p> <p>if <i>storev</i> = 'R', <i>nv</i> = <i>l</i>.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i>.</p> <p>If <i>storev</i> = 'C', $ldv \geq l$; if <i>storev</i> = 'R', $ldv \geq k$.</p>
<i>t</i>	<p>REAL for slarzb</p> <p>DOUBLE PRECISION for dlarzb</p> <p>COMPLEX for clarzb</p> <p>DOUBLE COMPLEX for zlarzb</p> <p>Array, DIMENSION (<i>ldt</i>, <i>k</i>). The triangular <i>k</i>-by-<i>k</i> matrix <i>T</i> in the representation of the block reflector.</p>
<i>ldt</i>	<p>INTEGER. The leading dimension of the array <i>t</i>.</p> <p>$ldt \geq k$.</p>
<i>c</i>	<p>REAL for slarzb</p> <p>DOUBLE PRECISION for dlarzb</p> <p>COMPLEX for clarzb</p> <p>DOUBLE COMPLEX for zlarzb</p> <p>Array, DIMENSION (<i>ldc</i>, <i>n</i>). On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.</p>
<i>ldc</i>	<p>INTEGER. The leading dimension of the array <i>c</i>.</p> <p>$ldc \geq \max(1, m)$.</p>
<i>work</i>	REAL for slarzb

DOUBLE PRECISION for dlarzb

COMPLEX for clarzb

DOUBLE COMPLEX for zlarzb

Workspace array, DIMENSION (*ldwork*, *k*).

ldwork

INTEGER. The leading dimension of the array *work*.

If *side* = 'L', $ldwork \geq \max(1, n)$;

if *side* = 'R', $ldwork \geq \max(1, m)$.

Output Parameters

c

On exit, *C* is overwritten by H^*C , or $H^T/H^H C$, or C^*H , or C^*H^T/H^H .

?larzt

Forms the triangular factor *T* of a block reflector $H = I - V^*T^*V^H$.

Syntax

call slarzt(*direct*, *storev*, *n*, *k*, *v*, *ldv*, *tau*, *t*, *ldt*)

call dlarzt(*direct*, *storev*, *n*, *k*, *v*, *ldv*, *tau*, *t*, *ldt*)

call clarzt(*direct*, *storev*, *n*, *k*, *v*, *ldv*, *tau*, *t*, *ldt*)

call zlarzt(*direct*, *storev*, *n*, *k*, *v*, *ldv*, *tau*, *t*, *ldt*)

Include Files

- mkl.fi

Description

The routine forms the triangular factor *T* of a real/complex block reflector *H* of order $> n$, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', $H = H(1)^*H(2)^*\dots H(k)$, and *T* is upper triangular.

If *direct* = 'B', $H = H(k)^*\dots H(2)^*H(1)$, and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th column of the array *v*, and $H = I - V^*T^*V^T$ (for real flavors) or $H = I - V^*T^*V^H$ (for complex flavors).

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th row of the array *v*, and $H = I - V^T^*T^*V$ (for real flavors) or $H = I - V^H^*T^*V$ (for complex flavors).

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

direct

CHARACTER*1.

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

If *direct* = 'F': $H = H(1)^*H(2)^*\dots H(k)$ (forward, not supported)

	<p>If <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)</p>
<i>storev</i>	<p>CHARACTER*1.</p> <p>Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below):</p> <p>If <i>storev</i> = 'C': column-wise (not supported)</p> <p>If <i>storev</i> = 'R': row-wise</p>
<i>n</i>	<p>INTEGER. The order of the block reflector H. $n \geq 0$.</p>
<i>k</i>	<p>INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.</p>
<i>v</i>	<p>REAL for slarzt</p> <p>DOUBLE PRECISION for dlarzt</p> <p>COMPLEX for clarzt</p> <p>DOUBLE COMPLEX for zlarzt</p> <p>Array, DIMENSION</p> <p>(<i>ldv</i>, <i>k</i>) if <i>storev</i> = 'C'</p> <p>(<i>ldv</i>, <i>n</i>) if <i>storev</i> = 'R' The matrix V.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array v.</p> <p>If <i>storev</i> = 'C', $ldv \geq \max(1, n)$;</p> <p>if <i>storev</i> = 'R', $ldv \geq k$.</p>
<i>tau</i>	<p>REAL for slarzt</p> <p>DOUBLE PRECISION for dlarzt</p> <p>COMPLEX for clarzt</p> <p>DOUBLE COMPLEX for zlarzt</p> <p>Array, DIMENSION (<i>k</i>). <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$.</p>
<i>ldt</i>	<p>INTEGER. The leading dimension of the output array t.</p> <p>$ldt \geq k$.</p>

Output Parameters

<i>t</i>	<p>REAL for slarzt</p> <p>DOUBLE PRECISION for dlarzt</p> <p>COMPLEX for clarzt</p> <p>DOUBLE COMPLEX for zlarzt</p> <p>Array, DIMENSION (<i>ldt</i>, <i>k</i>). The k-by-k triangular factor T of the block reflector. If <i>direct</i> = 'F', T is upper triangular; if <i>direct</i> = 'B', T is lower triangular. The rest of the array is not used.</p>
----------	---

V The matrix V . See *Application Notes* below.

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

`direct = 'F' and storev = 'C':` `direct = 'F' and storev = 'R':`

$$V = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ \cdot & 1 & \cdot \\ \cdot & \cdot & 1 \end{bmatrix}$$

$$\begin{array}{c} \text{---}V\text{---} \\ / \qquad \backslash \end{array} \begin{bmatrix} v_1 & v_1 & v_1 & v_1 & v_1 & \cdot & \cdot & \cdot & \cdot & 1 \\ v_2 & v_2 & v_2 & v_2 & v_2 & \cdot & \cdot & \cdot & \cdot & 1 \\ v_3 & v_3 & v_3 & v_3 & v_3 & \cdot & \cdot & \cdot & 1 & \cdot \end{bmatrix}$$

`direct = 'B' and storev = 'C':` `direct = 'B' and storev = 'R':`

$$\begin{array}{c} \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ \cdot & 1 & \cdot \\ \cdot & \cdot & 1 \end{array}$$

$$\begin{array}{c} \text{---}V\text{---} \\ / \qquad \backslash \end{array} \begin{bmatrix} 1 & \cdot & \cdot & \cdot & \cdot & v_1 & v_1 & v_1 & v_1 & v_1 \\ \cdot & 1 & \cdot & \cdot & \cdot & v_2 & v_2 & v_2 & v_2 & v_2 \\ \cdot & \cdot & 1 & \cdot & \cdot & v_3 & v_3 & v_3 & v_3 & v_3 \end{bmatrix}$$

$$V = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

?las2

Computes singular values of a 2-by-2 triangular matrix.

Syntax

```
call slas2( f, g, h, ssmín, ssmáx )
call dlas2( f, g, h, ssmín, ssmáx )
```

Include Files

- mkl.fi

Description

The routine ?las2 computes the singular values of the 2-by-2 matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, *ssmín* is the smaller singular value and *SSMAX* is the larger singular value.

Input Parameters

<i>f, g, h</i>	REAL for slas2 DOUBLE PRECISION for dlas2 The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.
----------------	---

Output Parameters

<i>ssmín, ssmáx</i>	REAL for slas2 DOUBLE PRECISION for dlas2 The smaller and the larger singular values, respectively.
---------------------	---

Application Notes

Barring over/underflow, all output quantities are correct to within a few units in the last place (*ulps*), even in the absence of a guard digit in addition/subtraction. In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows, or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?lascl

Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .

Syntax

```
call slascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
```

Description

The routine `?lascl` multiplies the m -by- n real/complex matrix A by the real scalar c_{to}/c_{from} . The operation is performed without over/underflow as long as the final result $c_{to}*A(i,j)/c_{from}$ does not over/underflow.

type specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

<i>type</i>	<p>CHARACTER*1. This parameter specifies the storage type of the input matrix.</p> <p>= 'G': A is a full matrix.</p> <p>= 'L': A is a lower triangular matrix.</p> <p>= 'U': A is an upper triangular matrix.</p> <p>= 'H': A is an upper Hessenberg matrix.</p> <p>= 'B': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the lower half stored</p> <p>= 'Q': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the upper half stored.</p> <p>= 'Z': A is a band matrix with lower bandwidth kl and upper bandwidth ku. See description of the <code>?gbtrf</code> function for storage details.</p>
<i>kl</i>	<p>INTEGER. The lower bandwidth of A. Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.</p>
<i>ku</i>	<p>INTEGER. The upper bandwidth of A. Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.</p>
<i>cfrom, cto</i>	<p>REAL for <code>slascl/clascl</code></p> <p>DOUBLE PRECISION for <code>dlascl/zlascl</code></p> <p>The matrix A is multiplied by $cto/cfrom$. $A(i,j)$ is computed without over/underflow if the final result $cto*A(i,j)/cfrom$ can be represented without over/underflow. <i>cfrom</i> must be nonzero.</p>
<i>m</i>	<p>INTEGER. The number of rows of the matrix A. $m \geq 0$.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A. $n \geq 0$.</p>
<i>a</i>	<p>REAL for <code>slascl</code></p> <p>DOUBLE PRECISION for <code>dlascl</code></p>

COMPLEX for `clascl`

DOUBLE COMPLEX for `zlascl`

Array, DIMENSION (lda, n) . The matrix to be multiplied by *cto/cfrom*. See *type* for the storage type.

lda

INTEGER. The leading dimension of the array *a*.

$lda \geq \max(1, m)$.

Output Parameters

a

The multiplied matrix *A*.

info

INTEGER.

If *info* = 0 - successful exit

If *info* = -*i* < 0, the *i*-th argument had an illegal value.

?lasd0

Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by [?bdsdc](#).

Syntax

```
call slasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
```

```
call dlasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
```

Include Files

- `mk1.fi`

Description

Using a divide and conquer approach, the routine [?lasd0](#) computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and offdiagonal e , where $m = n + sqre$.

The algorithm computes orthogonal matrices U and VT such that $B = U^* S^* VT$. The singular values S are overwritten on d .

The related subroutine [?lasda](#) computes only the singular values, and optionally, the singular vectors in compact form.

Input Parameters

n

INTEGER. On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array *d*.

sqre

INTEGER. Specifies the column dimension of the bidiagonal matrix.

If *sqre* = 0: the bidiagonal matrix has column dimension $m = n$.

If *sqre* = 1: the bidiagonal matrix has column dimension $m = n+1$.

<i>d</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION (<i>m</i> -1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. On entry, leading dimension of the output array <i>u</i> .
<i>ldvt</i>	INTEGER. On entry, leading dimension of the output array <i>vt</i> .
<i>smlsiz</i>	INTEGER. On entry, maximum size of the subproblems at the bottom of the computation tree.
<i>iwork</i>	INTEGER. Workspace array, dimension must be at least $(8n)$.
<i>work</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Workspace array, dimension must be at least $(3m^2+2m)$.

Output Parameters

<i>d</i>	On exit <i>d</i> , If <i>info</i> = 0, contains singular values of the bidiagonal matrix.
<i>u</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least (<i>ldq</i> , <i>n</i>). On exit, <i>u</i> contains the left singular vectors.
<i>vt</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least (<i>ldvt</i> , <i>m</i>). On exit, vt^T contains the right singular vectors.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value. If <i>info</i> = 1, a singular value did not converge.

?lasd1

Computes the SVD of an upper bidiagonal matrix *B* of the specified size. Used by ?bdsdc.

Syntax

```
call slasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork, work, info )
call dlasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork, work, info )
```

Include Files

- mkl.fi

Description

The routine computes the SVD of an upper bidiagonal n -by- m matrix B , where $n = nl + nr + 1$ and $m = n + sqre$.

The routine ?lasd1 is called from ?lasd0.

A related subroutine ?lasd7 handles the case in which the singular values (and the singular vectors in factored form) are desired.

?lasd1 computes the SVD as follows:

$$VT = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1^T & a & Z2^T & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) \ 0) * VT(out)$$

where $Z^T = (Z1^T a Z2^T b) = u^T * VT^T$, and u is a vector of dimension m with $alpha$ and $beta$ in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry b is empty if $sqre = 0$.

The left singular vectors of the original matrix are stored in u , and the transpose of the right singular vectors are stored in vt , and the singular values are in d . The algorithm consists of three stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the Z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine ?lasd2.
2. The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine ?lasd4 (as called by ?lasd3). This routine also calculates the singular vectors of the current problem.
3. The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

Input Parameters

nl	INTEGER. The row dimension of the upper block. $nl \geq 1$.
nr	INTEGER. The row dimension of the lower block. $nr \geq 1$.
$sqre$	INTEGER. If $sqre = 0$: the lower block is an nr -by- nr square matrix.

If $s_{qre} = 1$: the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + s_{qre}$.

<i>d</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION $(nl+nr+1)$. $n = nl+nr+1$. On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block; and $d(nl+2:n)$ contains the singular values of the lower block.</p>
<i>alpha</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Contains the diagonal element associated with the added row.</p>
<i>beta</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Contains the off-diagonal element associated with the added row.</p>
<i>u</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION (ldu, n). On entry $u(1:nl, 1:nl)$ contains the left singular vectors of the upper block; $u(nl+2:n, nl+2:n)$ contains the left singular vectors of the lower block.</p>
<i>ldu</i>	<p>INTEGER. The leading dimension of the array U.</p> <p>$ldu \geq \max(1, n)$.</p>
<i>vt</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Array, DIMENSION $(ldvt, m)$, where $m = n + s_{qre}$.</p> <p>On entry $vt(1:nl+1, 1:nl+1)^T$ contains the right singular vectors of the upper block; $vt(nl+2:m, nl+2:m)^T$ contains the right singular vectors of the lower block.</p>
<i>ldvt</i>	<p>INTEGER. The leading dimension of the array vt.</p> <p>$ldvt \geq \max(1, M)$.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION $(4n)$.</p>
<i>work</i>	<p>REAL for slasd1</p> <p>DOUBLE PRECISION for dlasd1</p> <p>Workspace array, DIMENSION $(3m_2 + 2m)$.</p>

Output Parameters

<i>d</i>	On exit $d(1:n)$ contains the singular values of the modified matrix.
----------	---

<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)})), I = 1, n$.
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)})), I = 1, n$.
<i>u</i>	On exit <i>u</i> contains the left singular vectors of the bidiagonal matrix.
<i>vt</i>	On exit <i>vt</i> ^T contains the right singular vectors of the bidiagonal matrix.
<i>idxq</i>	INTEGER Array, DIMENSION (<i>n</i>). Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, <i>d</i> (<i>idxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value. If <i>info</i> = 1, a singular value did not converge.

?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

Syntax

```
call slasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma, u2, ldu2,
vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )
```

```
call dlasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma, u2, ldu2,
vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )
```

Include Files

- mkl.fi

Description

The routine ?lasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

The routine ?lasd2 is called from ?lasd1.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.

<i>sqre</i>	<p>INTEGER.</p> <p>If <i>sqre</i> = 0): the lower block is an <i>nr</i>-by-<i>nr</i> square matrix</p> <p>If <i>sqre</i> = 1): the lower block is an <i>nr</i>-by-(<i>nr</i>+1) rectangular matrix. The bidiagonal matrix has $n = n_l + n_r + 1$ rows and $m = n + \text{sqre} \geq n$ columns.</p>
<i>d</i>	<p>REAL for <i>slasd2</i></p> <p>DOUBLE PRECISION for <i>dlsd2</i></p> <p>Array, DIMENSION (<i>n</i>). On entry <i>d</i> contains the singular values of the two submatrices to be combined.</p>
<i>alpha</i>	<p>REAL for <i>slasd2</i></p> <p>DOUBLE PRECISION for <i>dlsd2</i></p> <p>Contains the diagonal element associated with the added row.</p>
<i>beta</i>	<p>REAL for <i>slasd2</i></p> <p>DOUBLE PRECISION for <i>dlsd2</i></p> <p>Contains the off-diagonal element associated with the added row.</p>
<i>u</i>	<p>REAL for <i>slasd2</i></p> <p>DOUBLE PRECISION for <i>dlsd2</i></p> <p>Array, DIMENSION (<i>ldu</i>, <i>n</i>). On entry <i>u</i> contains the left singular vectors of two submatrices in the two square blocks with corners at (1,1), (<i>nl</i>, <i>nl</i>), and (<i>nl</i>+2, <i>nl</i>+2), (<i>n</i>,<i>n</i>).</p>
<i>ldu</i>	<p>INTEGER. The leading dimension of the array <i>u</i>.</p> <p>$ldu \geq n$.</p>
<i>ldu2</i>	<p>INTEGER. The leading dimension of the output array <i>u2</i>. $ldu2 \geq n$.</p>
<i>vt</i>	<p>REAL for <i>slasd2</i></p> <p>DOUBLE PRECISION for <i>dlsd2</i></p> <p>Array, DIMENSION (<i>ldvt</i>, <i>m</i>). On entry, vt^T contains the right singular vectors of two submatrices in the two square blocks with corners at (1,1), (<i>nl</i>+1, <i>nl</i>+1), and (<i>nl</i>+2, <i>nl</i>+2), (<i>m</i>, <i>m</i>).</p>
<i>ldvt</i>	<p>INTEGER. The leading dimension of the array <i>vt</i>. $ldvt \geq m$.</p>
<i>ldvt2</i>	<p>INTEGER. The leading dimension of the output array <i>vt2</i>. $ldvt2 \geq m$.</p>
<i>idxp</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>D</i> at the end of the array. On output <i>idxp</i>(2:<i>k</i>) points to the nondeflated <i>d</i>-values and <i>idxp</i>(<i>k</i>+1:<i>n</i>) points to the deflated singular values.</p>
<i>idx</i>	<p>INTEGER.</p>

Workspace array, `DIMENSION (n)`. This will contain the permutation used to sort the contents of d into ascending order.

coltyp

INTEGER.

Workspace array, `DIMENSION (n)`. As workspace, this array contains a label that indicates which of the following types a column in the $u2$ matrix or a row in the $vt2$ matrix is:

1 : non-zero in the upper half only

2 : non-zero in the lower half only

3 : dense

4 : deflated.

idxq

INTEGER. Array, `DIMENSION (n)`. This parameter contains the permutation that separately sorts the two sub-problems in D in the ascending order. Note that entries in the first half of this permutation must first be moved one position backwards and entries in the second half must have $n1+1$ added to their values.

Output Parameters

k

INTEGER. Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. $1 \leq k \leq n$.

d

On exit D contains the trailing $(n-k)$ updated singular values (those which were deflated) sorted into increasing order.

u

On exit u contains the trailing $(n-k)$ updated left singular vectors (those which were deflated) in its last $n-k$ columns.

z

REAL for `slasd2`

DOUBLE PRECISION for `dlsd2`

Array, `DIMENSION (n)`. On exit, z contains the updating row vector in the secular equation.

dsigma

REAL for `slasd2`

DOUBLE PRECISION for `dlsd2`

Array, `DIMENSION (n)`. Contains a copy of the diagonal elements ($k-1$ singular values and one zero) in the secular equation.

u2

REAL for `slasd2`

DOUBLE PRECISION for `dlsd2`

Array, `DIMENSION (ldu2, n)`. Contains a copy of the first $k-1$ left singular vectors which will be used by `?lasd3` in a matrix multiply (`?gemm`) to solve for the new left singular vectors. $u2$ is arranged into four blocks. The first block contains a column with 1 at $n1+1$ and zero everywhere else; the second block contains non-zero entries only at and above $n1$; the third contains non-zero entries only below $n1+1$; and the fourth is dense.

<code>vt</code>	On exit, vt^T contains the trailing $(n-k)$ updated right singular vectors (those which were deflated) in its last $n-k$ columns. In case <code>sqre = 1</code> , the last row of <code>vt</code> spans the right null space.
<code>vt2</code>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlsd2</code> Array, DIMENSION $(ldvt2, n)$. $vt2^T$ contains a copy of the first k right singular vectors which will be used by <code>?lasd3</code> in a matrix multiply (<code>?gemm</code>) to solve for the new right singular vectors. <code>vt2</code> is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in <i>sigma</i> ; the second block contains non-zeros only at and before $nl + 1$; the third block contains non-zeros only at and after $nl + 2$.
<code>idxc</code>	INTEGER. Array, DIMENSION (n) . This will contain the permutation used to arrange the columns of the deflated <i>u</i> matrix into three groups: the first group contains non-zero entries only at and above nl , the second contains non-zero entries only below $nl+2$, and the third is dense.
<code>coltyp</code>	On exit, it is an array of dimension 4, with <code>coltyp(i)</code> being the dimension of the <i>i</i> -th type columns.
<code>info</code>	INTEGER. If <code>info = 0</code>): successful exit If <code>info = -i < 0</code> , the <i>i</i> -th argument had an illegal value.

?lasd3

Finds square roots of the roots of the secular equation, as defined by the values in D and Z, and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.

Syntax

```
call slasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt, vt2,
ldvt2, idxc, ctot, z, info )
```

```
call dlsd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt, vt2,
ldvt2, idxc, ctot, z, info )
```

Include Files

- `mk1.fi`

Description

The routine `?lasd3` finds all the square roots of the roots of the secular equation, as defined by the values in *D* and *Z*.

It makes the appropriate calls to `?lasd4` and then updates the singular vectors by matrix multiplication.

The routine `?lasd3` is called from `?lasd1`.

Input Parameters

<i>nl</i>	<p>INTEGER. The row dimension of the upper block.</p> <p>$nl \geq 1$.</p>
<i>nr</i>	<p>INTEGER. The row dimension of the lower block.</p> <p>$nr \geq 1$.</p>
<i>sqr</i>	<p>INTEGER.</p> <p>If <i>sqr</i> = 0): the lower block is an <i>nr</i>-by-<i>nr</i> square matrix.</p> <p>If <i>sqr</i> = 1): the lower block is an <i>nr</i>-by-(<i>nr</i>+1) rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqr \geq n$ columns.</p>
<i>k</i>	<p>INTEGER. The size of the secular equation, $1 \leq k \leq n$.</p>
<i>q</i>	<p>REAL for slasd3</p> <p>DOUBLE PRECISION for dlasd3</p> <p>Workspace array, DIMENSION at least (<i>ldq</i>, <i>k</i>).</p>
<i>ldq</i>	<p>INTEGER. The leading dimension of the array <i>Q</i>.</p> <p>$ldq \geq k$.</p>
<i>dsigma</i>	<p>REAL for slasd3</p> <p>DOUBLE PRECISION for dlasd3</p> <p>Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.</p>
<i>ldu</i>	<p>INTEGER. The leading dimension of the array <i>u</i>.</p> <p>$ldu \geq n$.</p>
<i>u2</i>	<p>REAL for slasd3</p> <p>DOUBLE PRECISION for dlasd3</p> <p>Array, DIMENSION (<i>ldu2</i>, <i>n</i>).</p> <p>The first <i>k</i> columns of this matrix contain the non-deflated left singular vectors for the split problem.</p>
<i>ldu2</i>	<p>INTEGER. The leading dimension of the array <i>u2</i>.</p> <p>$ldu2 \geq n$.</p>
<i>ldvt</i>	<p>INTEGER. The leading dimension of the array <i>vt</i>.</p> <p>$ldvt \geq n$.</p>
<i>vt2</i>	<p>REAL for slasd3</p> <p>DOUBLE PRECISION for dlasd3</p> <p>Array, DIMENSION (<i>ldvt2</i>, <i>n</i>).</p>

The first k columns of $vt2'$ contain the non-deflated right singular vectors for the split problem.

ldvt2

INTEGER. The leading dimension of the array *vt2*.

ldvt2 $\geq n$.

idxc

INTEGER. Array, DIMENSION (n).

The permutation used to arrange the columns of u (and rows of vt) into three groups: the first group contains non-zero entries only at and above (or before) $n1 + 1$; the second contains non-zero entries only at and below (or after) $n1 + 2$; and the third is dense. The first column of u and the row of vt are treated separately, however. The rows of the singular vectors found by ?lasd4 must be likewise permuted before the matrix multiplies can take place.

ctot

INTEGER. Array, DIMENSION (4). A count of the total number of the various types of columns in u (or rows in vt), as described in *idxc*.

The fourth column type is any column which has been deflated.

z

REAL for *slasd3*

DOUBLE PRECISION for *dlasd3*

Array, DIMENSION (k). The first k elements of this array contain the components of the deflation-adjusted updating row vector.

Output Parameters

d

REAL for *slasd3*

DOUBLE PRECISION for *dlasd3*

Array, DIMENSION (k). On exit the square roots of the roots of the secular equation, in ascending order.

u

REAL for *slasd3*

DOUBLE PRECISION for *dlasd3*

Array, DIMENSION (ldu, n).

The last $n - k$ columns of this matrix contain the deflated left singular vectors.

vt

REAL for *slasd3*

DOUBLE PRECISION for *dlasd3*

Array, DIMENSION ($ldvt, m$).

The last $m - k$ columns of vt' contain the deflated right singular vectors.

vt2

Destroyed on exit.

z

Destroyed on exit.

info

INTEGER.

If *info* = 0): successful exit.

If $info = -i < 0$, the i -th argument had an illegal value.

If $info = 1$, an singular value did not converge.

Application Notes

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

?lasd4

Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd4( n, i, d, z, delta, rho, sigma, work, info)
call dlasd4( n, i, d, z, delta, rho, sigma, work, info )
```

Include Files

- mkl.fi

Description

The routine computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array d , and that $0 \leq d(i) < d(j)$ for $i < j$ and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T,$$

where the Euclidean norm of Z is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

n	INTEGER. The length of all arrays.
i	INTEGER. The index of the eigenvalue to be computed. $1 \leq i \leq n$.
d	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (n). The original eigenvalues. They must be in order, $0 \leq d(i) < d(j)$ for $i < j$.
z	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (n).

The components of the updating vector.

rho

REAL for slasd4

DOUBLE PRECISION for dlasd4

The scalar in the symmetric updating formula.

work

REAL for slasd4

DOUBLE PRECISION for dlasd4

Workspace array, DIMENSION (*n*).

If $n \neq 1$, *work* contains ($d(j) + \sigma_i$) in its *j*-th component.

If $n = 1$, then $work(1) = 1$.

Output Parameters

delta

REAL for slasd4

DOUBLE PRECISION for dlasd4

Array, DIMENSION (*n*).

If $n \neq 1$, *delta* contains ($d(j) - \sigma_i$) in its *j*-th component.

If $n = 1$, then $delta(1) = 1$. The vector *delta* contains the information necessary to construct the (singular) eigenvectors.

sigma

REAL for slasd4

DOUBLE PRECISION for dlasd4

The computed σ_i , the *i*-th updated eigenvalue.

info

INTEGER.

= 0: successful exit

> 0: If $info = 1$, the updating process failed.

?lasd5

Computes the square root of the i-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd5( i, d, z, delta, rho, dsigma, work )
```

```
call dlasd5( i, d, z, delta, rho, dsigma, work )
```

Include Files

- mkl.fi

Description

The routine computes the square root of the *i*-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T$

The diagonal entries in the array d must satisfy $0 \leq d(i) < d(j)$ for $i < j$, ρ must be greater than 0, and that the Euclidean norm of the vector Z is equal to 1.

Input Parameters

i	<i>INTEGER</i> . The index of the eigenvalue to be computed. $i = 1$ or $i = 2$.
d	REAL for slasd5 DOUBLE PRECISION for dlasd5 Array, dimension (2). The original eigenvalues, $0 \leq d(1) < d(2)$.
z	REAL for slasd5 DOUBLE PRECISION for dlasd5 Array, dimension (2). The components of the updating vector.
ρ	REAL for slasd5 DOUBLE PRECISION for dlasd5 The scalar in the symmetric updating formula.
$work$	REAL for slasd5 DOUBLE PRECISION for dlasd5. Workspace array, dimension (2). Contains $(d(j) + \sigma_i)$ in its j -th component.

Output Parameters

δ	REAL for slasd5 DOUBLE PRECISION for dlasd5. Array, dimension (2). Contains $(d(j) - \sigma_i)$ in its j -th component. The vector δ contains the information necessary to construct the eigenvectors.
σ_i	REAL for slasd5 DOUBLE PRECISION for dlasd5. The computed σ_i , the i -th updated eigenvalue.

?lasd6

Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.

Syntax

```
call slasd6( icompr, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork, info )
```

```
call dlasd6( icompg, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr, givcol,
ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork, info )
```

Description

The routine `?lasd6` computes the *SVD* of an updated upper bidiagonal matrix B obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. B is an n -by- m matrix with $n = nl + nr + 1$ and $m = n + sqre$. A related subroutine, `?lasd1`, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. `?lasd6` computes the *SVD* as follows:

$$B = U(in) \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$= U(out) * (D(out) * VT(out))$

where $Z' = (Z1' \ a \ Z2' \ b) = u' * VT'$, and u is a vector of dimension m with $alpha$ and $beta$ in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry b is empty if $sqre = 0$.

The singular values of B can be computed using $D1$, $D2$, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in vf and vl , respectively, in `?lasd6`. Hence U and VT are not explicitly referenced.

The singular values are stored in D . The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the Z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd7`.
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine `?lasd4` (as called by `?lasd8`). This routine also updates vf and vl and computes the distances between the updated singular values and the old singular values. `?lasd6` is called from `?lasda`.

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only = 1: Compute singular vectors in factored form as well.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER .

= 0: the lower block is an nr -by- nr square matrix.

= 1: the lower block is an nr -by- $(nr+1)$ rectangular matrix.

The bidiagonal matrix has row dimension $n=nl+nr+1$, and column dimension $m = n + sqre$.

<i>d</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Array, dimension ($nl+nr+1$). On entry $d(1:nl,1:nl)$ contains the singular values of the upper block, and $d(nl+2:n)$ contains the singular values of the lower block.</p>
<i>vf</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Array, dimension (m).</p> <p>On entry, $vf(1:nl+1)$ contains the first components of all right singular vectors of the upper block; and $vf(nl+2:m)$ contains the first components of all right singular vectors of the lower block.</p>
<i>vl</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Array, dimension (m).</p> <p>On entry, $vl(1:nl+1)$ contains the last components of all right singular vectors of the upper block; and $vl(nl+2:m)$ contains the last components of all right singular vectors of the lower block.</p>
<i>alpha</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Contains the diagonal element associated with the added row.</p>
<i>beta</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Contains the off-diagonal element associated with the added row.</p>
<i>ldgcol</i>	<p>INTEGER. The leading dimension of the output array <i>givcol</i>, must be at least n.</p>
<i>ldgnum</i>	<p>INTEGER.</p> <p>The leading dimension of the output arrays <i>givnum</i> and <i>poles</i>, must be at least n.</p>
<i>work</i>	<p>REAL for slasd6</p> <p>DOUBLE PRECISION for dlasd6</p> <p>Workspace array, dimension ($4m$).</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, dimension ($3n$).</p>

Output Parameters

<i>d</i>	On exit <i>d</i> (1: <i>n</i>) contains the singular values of the modified matrix.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), \text{I} = 1, n$.
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), \text{I} = 1, n$.
<i>idxq</i>	INTEGER. Array, dimension (<i>n</i>). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, <i>d</i> (<i>idxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>perm</i>	INTEGER. Array, dimension (<i>n</i>). The permutations (from deflation and sorting) to be applied to each block. Not referenced if <i>icompq</i> = 0.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompq</i> = 0.
<i>givcol</i>	INTEGER. Array, dimension (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>givnum</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>ldgnum</i> , 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>poles</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>ldgnum</i> , 2). On exit, <i>poles</i> (1,*) is an array containing the new singular values obtained from solving the secular equation, and <i>poles</i> (2,*) is an array containing the poles in the secular equation. Not referenced if <i>icompq</i> = 0.
<i>difl</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>n</i>). On exit, <i>difl</i> (<i>i</i>) is the distance between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> -th (undeflated) old singular value.
<i>difr</i>	REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension (*ldgnum*, 2) if *icompq* = 1 and dimension (*n*) if *icompq* = 0.

On exit, *difr*(*i*, 1) is the distance between *i*-th updated (undeflated) singular value and the *i*+1-th (undeflated) old singular value. If *icompq* = 1, *difr*(1: *k*, 2) is an array containing the normalizing factors for the right singular vector matrix.

See ?lasd8 for details on *difl* and *difr*.

z

REAL for slasd6

DOUBLE PRECISION for dlasd6

Array, dimension (*m*).

The first elements of this array contain the components of the deflation-adjusted updating row vector.

k

INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.

c

REAL for slasd6

DOUBLE PRECISION for dlasd6

c contains garbage if *sqre* = 0 and the C-value of a Givens rotation related to the right null space if *sqre* = 1.

s

REAL for slasd6

DOUBLE PRECISION for dlasd6

s contains garbage if *sqre* = 0 and the S-value of a Givens rotation related to the right null space if *sqre* = 1.

info

INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: if *info* = 1, an singular value did not converge

?lasd7

Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

Syntax

```
call slasd7( icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta, dsigma,
            idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s, info )
```

```
call dlasd7( icompq, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta, dsigma,
            idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s, info )
```

Include Files

Description

The routine `?lasd7` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one. `?lasd7` is called from `?lasd6`.

Input Parameters

<i>icompq</i>	<p>INTEGER. Specifies whether singular vectors are to be computed in compact form, as follows:</p> <p>= 0: Compute singular values only.</p> <p>= 1: Compute singular vectors of upper bidiagonal matrix in compact form.</p>
<i>nl</i>	<p>INTEGER. The row dimension of the upper block.</p> <p>$nl \geq 1$.</p>
<i>nr</i>	<p>INTEGER. The row dimension of the lower block.</p> <p>$nr \geq 1$.</p>
<i>scre</i>	<p>INTEGER.</p> <p>= 0: the lower block is an nr-by-nr square matrix.</p> <p>= 1: the lower block is an nr-by-$(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + scre \geq n$ columns.</p>
<i>d</i>	<p>REAL for <code>slasd7</code></p> <p>DOUBLE PRECISION for <code>dlasd7</code></p> <p>Array, DIMENSION (n). On entry d contains the singular values of the two submatrices to be combined.</p>
<i>zw</i>	<p>REAL for <code>slasd7</code></p> <p>DOUBLE PRECISION for <code>dlasd7</code></p> <p>Array, DIMENSION (m).</p> <p>Workspace for z.</p>
<i>vf</i>	<p>REAL for <code>slasd7</code></p> <p>DOUBLE PRECISION for <code>dlasd7</code></p> <p>Array, DIMENSION (m). On entry, $vf(1:nl+1)$ contains the first components of all right singular vectors of the upper block; and $vf(nl+2:m)$ contains the first components of all right singular vectors of the lower block.</p>
<i>vfw</i>	<p>REAL for <code>slasd7</code></p> <p>DOUBLE PRECISION for <code>dlasd7</code></p> <p>Array, DIMENSION (m).</p>

	Workspace for <i>vf</i> .
<i>vl</i>	<p>REAL for <i>slasd7</i></p> <p>DOUBLE PRECISION for <i>dlsd7</i></p> <p>Array, DIMENSION (<i>m</i>).</p> <p>On entry, <i>vl</i>(1:<i>nl</i>+1) contains the last components of all right singular vectors of the upper block; and <i>vl</i>(<i>nl</i>+2:<i>m</i>) contains the last components of all right singular vectors of the lower block.</p>
<i>VLW</i>	<p>REAL for <i>slasd7</i></p> <p>DOUBLE PRECISION for <i>dlsd7</i></p> <p>Array, DIMENSION (<i>m</i>).</p> <p>Workspace for <i>VL</i>.</p>
<i>alpha</i>	<p>REAL for <i>slasd7</i></p> <p>DOUBLE PRECISION for <i>dlsd7</i>.</p> <p>Contains the diagonal element associated with the added row.</p>
<i>beta</i>	<p>REAL for <i>slasd7</i></p> <p>DOUBLE PRECISION for <i>dlsd7</i></p> <p>Contains the off-diagonal element associated with the added row.</p>
<i>idx</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.</p>
<i>idxp</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>d</i> at the end of the array.</p>
<i>idxq</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>This contains the permutation which separately sorts the two sub-problems in <i>d</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have <i>nl</i>+1 added to their values.</p>
<i>ldgcol</i>	<p>INTEGER. The leading dimension of the output array <i>givcol</i>, must be at least <i>n</i>.</p>
<i>ldgnum</i>	<p>INTEGER. The leading dimension of the output array <i>givnum</i>, must be at least <i>n</i>.</p>

Output Parameters

<i>k</i>	<p>INTEGER. Contains the dimension of the non-deflated matrix, this is the order of the related secular equation.</p>
----------	---

	$1 \leq k \leq n$.
<i>d</i>	On exit, <i>d</i> contains the trailing (<i>n-k</i>) updated singular values (those which were deflated) sorted into increasing order.
<i>z</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>m</i>). On exit, <i>Z</i> contains the updating row vector in the secular equation.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>dsigma</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>n</i>). Contains a copy of the diagonal elements (<i>k-1</i> singular values and one zero) in the secular equation.
<i>idxp</i>	On output, <i>idxp</i> (2: <i>k</i>) points to the nondeflated <i>d</i> -values and <i>idxp</i> (<i>k+1:n</i>) points to the deflated singular values.
<i>perm</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if <i>icompq</i> = 0.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompq</i> = 0.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>givnum</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7. Array, DIMENSION (<i>ldgnum</i> , 2). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>c</i>	REAL for slasd7. DOUBLE PRECISION for dlasd7. If <i>sgre</i> = 0, then <i>c</i> contains garbage, and if <i>sgre</i> = 1, then <i>c</i> contains C-value of a Givens rotation related to the right null space.
<i>S</i>	REAL for slasd7.

DOUBLE PRECISION for dlasd7.

If *sgre* = 0, then *s* contains garbage, and if *sgre* = 1, then *s* contains *S*-value of a Givens rotation related to the right null space.

info

INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?lasd8

*Finds the square roots of the roots of the secular equation, and stores, for each element in *D*, the distance to its two nearest poles. Used by ?bdsdc.*

Syntax

```
call slasd8( icompg, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info )
```

```
call dlasd8( icompg, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info )

Description

The routine ?lasd8 finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to ?lasd4, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd8 is called from ?lasd6.

Input Parameters

icompg

INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine:

= 0: Compute singular values only.

= 1: Compute singular vectors in factored form as well.

k

INTEGER. The number of terms in the rational function to be solved by ?lasd4. $k \geq 1$.

z

REAL for slasd8

DOUBLE PRECISION for dlasd8.

Array, DIMENSION (*k*).

The first *k* elements of this array contain the components of the deflation-adjusted updating row vector.

vf

REAL for slasd8

DOUBLE PRECISION for dlasd8.

Array, DIMENSION (*k*).

On entry, *vf* contains information passed through dbede8.

<i>vl</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Array, DIMENSION (<i>k</i>). On entry, <i>vl</i> contains information passed through <i>dbede8</i>.</p>
<i>lddifr</i>	<p>INTEGER. The leading dimension of the output array <i>difr</i>, must be at least <i>k</i>.</p>
<i>dsigma</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Array, DIMENSION (<i>k</i>).</p> <p>The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.</p>
<i>work</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Workspace array, DIMENSION at least (3<i>k</i>).</p>

Output Parameters

<i>d</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Array, DIMENSION (<i>k</i>).</p> <p>On output, <i>D</i> contains the updated singular values.</p>
<i>z</i>	Updated on exit.
<i>vf</i>	On exit, <i>vf</i> contains the first <i>k</i> components of the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the first <i>k</i> components of the last components of all right singular vectors of the bidiagonal matrix.
<i>difl</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Array, DIMENSION (<i>k</i>). On exit, $difl(i) = d(i) - dsigma(i)$.</p>
<i>difr</i>	<p>REAL for <i>slasd8</i></p> <p>DOUBLE PRECISION for <i>dlasd8</i>.</p> <p>Array,</p> <p>DIMENSION (<i>lddifr</i>, 2) if <i>icompq</i> = 1 and</p> <p>DIMENSION (<i>k</i>) if <i>icompq</i> = 0.</p> <p>On exit, $difr(i,1) = d(i) - dsigma(i+1)$, $difr(k,1)$ is not defined and will not be referenced. If <i>icompq</i> = 1, $difr(1:k,2)$ is an array containing the normalizing factors for the right singular vector matrix.</p>
<i>dsigma</i>	The elements of this array may be very slightly altered in value.

info INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: If *info* = 1, an singular value did not converge.

?lasd9

Finds the square roots of the roots of the secular equation, and stores, for each element in D, the distance to its two nearest poles. Used by ?bdsdc.

Syntax

```
call slasd9( icipq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
call dlasd9( icipq, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
```

Include Files

- mkl.fi

Description

The routine ?lasd9 finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to ?lasd4, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd9 is called from ?lasd7.

Input Parameters

icipq INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine:

If *icipq* = 0, compute singular values only;

If *icipq* = 1, compute singular vector matrices in factored form also.

k INTEGER. The number of terms in the rational function to be solved by slasd4. $k \geq 1$.

dsigma REAL for slasd9
DOUBLE PRECISION for dlasd9.
Array, DIMENSION(*k*).
The first *k* elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

z REAL for slasd9
DOUBLE PRECISION for dlasd9.
Array, DIMENSION (*k*). The first *k* elements of this array contain the components of the deflation-adjusted updating row vector.

vf REAL for slasd9
DOUBLE PRECISION for dlasd9.

Array, $\text{DIMENSION}(k)$. On entry, vf contains information passed through `sbede8`.

vl

REAL for `slasd9`

DOUBLE PRECISION for `dlsd9`.

Array, $\text{DIMENSION}(k)$. On entry, vl contains information passed through `sbede8`.

$work$

REAL for `slasd9`

DOUBLE PRECISION for `dlsd9`.

Workspace array, DIMENSION at least $(3k)$.

Output Parameters

d

REAL for `slasd9`

DOUBLE PRECISION for `dlsd9`.

Array, $\text{DIMENSION}(k)$. $d(i)$ contains the updated singular values.

vf

On exit, vf contains the first k components of the first components of all right singular vectors of the bidiagonal matrix.

vl

On exit, vl contains the first k components of the last components of all right singular vectors of the bidiagonal matrix.

$difl$

REAL for `slasd9`

DOUBLE PRECISION for `dlsd9`.

Array, $\text{DIMENSION}(k)$.

On exit, $difl(i) = d(i) - dsigma(i)$.

$difr$

REAL for `slasd9`

DOUBLE PRECISION for `dlsd9`.

Array,

$\text{DIMENSION}(ldu, 2)$ if $icompq = 1$ and

$\text{DIMENSION}(k)$ if $icompq = 0$.

On exit, $difr(i, 1) = d(i) - dsigma(i+1)$, $difr(k, 1)$ is not defined and will not be referenced.

If $icompq = 1$, $difr(1:k, 2)$ is an array containing the normalizing factors for the right singular vector matrix.

$info$

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0: If $info = 1$, an singular value did not converge

?lasda

Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasda( icompg, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z, poles,
givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )

call dlasda( icompg, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z, poles,
givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
```

Include Files

- mkl.fi

Description

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e , where $m = n + sqre$.

The algorithm computes the singular values in the $SVDB = U^*S^*VT$. The orthogonal matrices U and VT are optionally computed in compact form. A related subroutine ?lasd0 computes the singular values and the singular vectors in explicit form.

Input Parameters

<i>icompg</i>	<p>INTEGER.</p> <p>Specifies whether singular vectors are to be computed in compact form, as follows:</p> <p>= 0: Compute singular values only.</p> <p>= 1: Compute singular vectors of upper bidiagonal matrix in compact form.</p>
<i>smlsiz</i>	<p>INTEGER.</p> <p>The maximum size of the subproblems at the bottom of the computation tree.</p>
<i>n</i>	<p>INTEGER. The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array d.</p>
<i>sqre</i>	<p>INTEGER. Specifies the column dimension of the bidiagonal matrix.</p> <p>If $sqre = 0$: the bidiagonal matrix has column dimension $m = n$</p> <p>If $sqre = 1$: the bidiagonal matrix has column dimension $m = n + 1$.</p>
<i>d</i>	<p>REAL for slasda</p> <p>DOUBLE PRECISION for dlasda.</p> <p>Array, DIMENSION (n). On entry, d contains the main diagonal of the bidiagonal matrix.</p>
<i>e</i>	<p>REAL for slasda</p> <p>DOUBLE PRECISION for dlasda.</p>

Array, `DIMENSION ($m - 1$)`. Contains the subdiagonal entries of the bidiagonal matrix. On exit, *e* is destroyed.

ldu INTEGER. The leading dimension of arrays *u*, *vt*, *difl*, *difr*, *poles*, *givnum*, and *z*. $ldu \geq n$.

ldgcol INTEGER. The leading dimension of arrays *givcol* and *perm*. $ldgcol \geq n$.

work REAL for *slasda*

DOUBLE PRECISION for *dlasda*.

Workspace array, `DIMENSION ($6n + (smlsiz+1)^2$)`.

iwork INTEGER.

Workspace array, *Dimension* must be at least $(7n)$.

Output Parameters

d On exit *d*, if *info* = 0, contains the singular values of the bidiagonal matrix.

u REAL for *slasda*

DOUBLE PRECISION for *dlasda*.

Array, `DIMENSION (ldu, smlsiz)` if *icompq* = 1.

Not referenced if *icompq* = 0.

If *icompq* = 1, on exit, *u* contains the left singular vector matrices of all subproblems at the bottom level.

vt REAL for *slasda*

DOUBLE PRECISION for *dlasda*.

Array, `DIMENSION (ldu, smlsiz+1)` if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, *vt'* contains the right singular vector matrices of all subproblems at the bottom level.

k INTEGER.

Array, `DIMENSION (n)` if *icompq* = 1 and

`DIMENSION (1)` if *icompq* = 0.

If *icompq* = 1, on exit, *k*(*i*) is the dimension of the *i*-th secular equation on the computation tree.

difl REAL for *slasda*

DOUBLE PRECISION for *dlasda*.

Array, `DIMENSION (ldu, nlvl)`,

where $nlvl = \text{floor}(\log_2(n/smlsiz))$.

difr REAL for *slasda*

DOUBLE PRECISION for *dlasda*.

Array,

DIMENSION (*ldu*, 2 *nlvl*) if *icompq* = 1 and

DIMENSION (*n*) if *icompq* = 0.

If *icompq* = 1, on exit, *difl*(1:*n*, *i*) and *difr*(1:*n*, 2*i* - 1) record distances between singular values on the *i*-th level and singular values on the (*i* - 1)-th level, and *difr*(1:*n*, 2*i*) contains the normalizing factors for the right singular vector matrix. See ?lasd8 for details.

z

REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (*ldu*, *nlvl*) if *icompq* = 1 and

DIMENSION (*n*) if *icompq* = 0. The first *k* elements of *z*(1, *i*) contain the components of the deflation-adjusted updating row vector for subproblems on the *i*-th level.

poles

REAL for slasda

DOUBLE PRECISION for dlasda

Array, DIMENSION(*ldu*, 2**nlvl*)

if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, *poles*(1, 2*i* - 1) and *poles*(1, 2*i*) contain the new and old singular values involved in the secular equations on the *i*-th level.

givptr

INTEGER. Array, DIMENSION (*n*) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, *givptr*(*i*) records the number of Givens rotations performed on the *i*-th problem on the computation tree.

givcol

INTEGER .

Array, DIMENSION(*ldgcol*, 2**nlvl*) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, for each *i*, *givcol*(1, 2 *i* - 1) and *givcol*(1, 2 *i*) record the locations of Givens rotations performed on the *i*-th level on the computation tree.

perm

INTEGER . Array, DIMENSION (*ldgcol*, *nlvl*) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, *perm* (1, *i*) records permutations done on the *i*-th level of the computation tree.

givnum

REAL for slasda

DOUBLE PRECISION for dlasda.

Array DIMENSION (*ldu*, 2**nlvl*) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, for each *i*, *givnum*(1, 2 *i* - 1) and *givnum*(1, 2 *i*) record the C- and S-values of Givens rotations performed on the *i*-th level on the computation tree.

c

REAL for slasda

DOUBLE PRECISION for dlasda.

Array,

DIMENSION (*n*) if *icompq* = 1, and

DIMENSION (1) if $icompg = 0$.

If $icompg = 1$ and the i -th subproblem is not square, on exit, $c(i)$ contains the C -value of a Givens rotation related to the right null space of the i -th subproblem.

s

REAL for `slasda`

DOUBLE PRECISION for `dlasda`.

Array,

DIMENSION (n) $icompg = 1$, and

DIMENSION (1) if $icompg = 0$.

If $icompg = 1$ and the i -th subproblem is not square, on exit, $s(i)$ contains the S -value of a Givens rotation related to the right null space of the i -th subproblem.

$info$

INTEGER.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value

> 0: If $info = 1$, an singular value did not converge

?lasdq

Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info )
```

```
call dlasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info )
```

Include Files

- `mkl.fi`

Description

The routine `?lasdq` computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal d and off-diagonal e , accumulating the transformations if desired. If B is the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that $B = Q^* S P^T$. The singular values S are overwritten on d .

The input matrix U is changed to $U^* Q$ if desired.

The input matrix VT is changed to $P^T VT$ if desired.

The input matrix C is changed to $Q^T C$ if desired.

Input Parameters

$uplo$

CHARACTER*1. On entry, $uplo$ specifies whether the input bidiagonal matrix is upper or lower bidiagonal.

If *uplo* = 'U' or 'u', *B* is upper bidiagonal;

If *uplo* = 'L' or 'l', *B* is lower bidiagonal.

sqr

INTEGER.

= 0: then the input matrix is *n*-by-*n*.

= 1: then the input matrix is *n*-by-(*n*+1) if *uplu* = 'U' and (*n*+1)-by-*n* if *uplu*

= 'L'. The bidiagonal matrix has $n = n_l + n_r + 1$ rows and $m = n + \text{sqr} \geq n$ columns.

n

INTEGER. On entry, *n* specifies the number of rows and columns in the matrix. *n* must be at least 0.

ncvt

INTEGER. On entry, *ncvt* specifies the number of columns of the matrix *VT*. *ncvt* must be at least 0.

nru

INTEGER. On entry, *nru* specifies the number of rows of the matrix *U*. *nru* must be at least 0.

ncc

INTEGER. On entry, *ncc* specifies the number of columns of the matrix *C*. *ncc* must be at least 0.

d

REAL for *slasdq*

DOUBLE PRECISION for *dlsdq*.

Array, DIMENSION (*n*). On entry, *d* contains the diagonal entries of the bidiagonal matrix.

e

REAL for *slasdq*

DOUBLE PRECISION for *dlsdq*.

Array, DIMENSION is (*n*-1) if *sqr* = 0 and *n* if *sqr* = 1. On entry, the entries of *e* contain the off-diagonal entries of the bidiagonal matrix.

vt

REAL for *slasdq*

DOUBLE PRECISION for *dlsdq*.

Array, DIMENSION (*ldvt*, *ncvt*). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension *n*-by-*ncvt* if *sqr* = 0 and (*n*+1)-by-*ncvt* if *sqr* = 1 (not referenced if *ncvt*=0).

ldvt

INTEGER. On entry, *ldvt* specifies the leading dimension of *vt* as declared in the calling (sub) program. *ldvt* must be at least 1. If *ncvt* is nonzero, *ldvt* must also be at least *n*.

u

REAL for *slasdq*

DOUBLE PRECISION for *dlsdq*.

Array, DIMENSION (*ldu*, *n*). On entry, contains a matrix which on exit has been postmultiplied by *Q*, dimension *nru*-by-*n* if *sqr* = 0 and *nru*-by-(*n*+1) if *sqr* = 1 (not referenced if *nru*=0).

<i>ldu</i>	INTEGER. On entry, <i>ldu</i> specifies the leading dimension of <i>u</i> as declared in the calling (sub) program. <i>ldu</i> must be at least $\max(1, nru)$.
<i>c</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlsdq</i> . Array, DIMENSION (<i>ldc</i> , <i>ncc</i>). On entry, contains an <i>n</i> -by- <i>ncc</i> matrix which on exit has been premultiplied by Q' , dimension <i>n</i> -by- <i>ncc</i> if <i>sqr</i> = 0 and (<i>n</i> +1)-by- <i>ncc</i> if <i>sqr</i> = 1 (not referenced if <i>ncc</i> =0).
<i>ldc</i>	INTEGER. On entry, <i>ldc</i> specifies the leading dimension of <i>C</i> as declared in the calling (sub) program. <i>ldc</i> must be at least 1. If <i>ncc</i> is non-zero, <i>ldc</i> must also be at least <i>n</i> .
<i>work</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlsdq</i> . Array, DIMENSION (4 <i>n</i>). This is a workspace array. Only referenced if one of <i>ncvt</i> , <i>nru</i> , or <i>ncc</i> is nonzero, and if <i>n</i> is at least 2.

Output Parameters

<i>d</i>	On normal exit, <i>d</i> contains the singular values in ascending order.
<i>e</i>	On normal exit, <i>e</i> will contain 0. If the algorithm does not converge, <i>d</i> and <i>e</i> will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.
<i>vt</i>	On exit, the matrix has been premultiplied by P' .
<i>u</i>	On exit, the matrix has been postmultiplied by Q .
<i>c</i>	On exit, the matrix has been premultiplied by Q' .
<i>info</i>	INTEGER. On exit, a value of 0 indicates a successful exit. If <i>info</i> < 0, argument number <i>-info</i> is illegal. If <i>info</i> > 0, the algorithm did not converge, and <i>info</i> specifies how many superdiagonals did not converge.

?lasdt

Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.

Syntax

```
call slasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
call dlasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
```

Include Files

- `mkl.fi`

Description

The routine creates a tree of subproblems for bidiagonal divide and conquer.

Input Parameters

<i>n</i>	INTEGER. On entry, the number of diagonal elements of the bidiagonal matrix.
<i>msub</i>	INTEGER. On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Output Parameters

<i>lvl</i>	INTEGER. On exit, the number of levels on the computation tree.
<i>nd</i>	INTEGER. On exit, the number of nodes on the tree.
<i>inode</i>	INTEGER. Array, DIMENSION (<i>n</i>). On exit, centers of subproblems.
<i>ndiml</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of left children.
<i>ndimr</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of right children.

?laset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
call slaset( uplo, m, n, alpha, beta, a, lda )
call dlaset( uplo, m, n, alpha, beta, a, lda )
call claset( uplo, m, n, alpha, beta, a, lda )
call zlaset( uplo, m, n, alpha, beta, a, lda )
```

Include Files

- mkl.fi

Description

The routine initializes an *m*-by-*n* matrix *A* to *beta* on the diagonal and *alpha* on the off-diagonals.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix <i>A</i> to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of <i>A</i> is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of <i>A</i> is not changed.
-------------	---

Otherwise: All of the matrix A is set.

m INTEGER. The number of rows of the matrix A . $m \geq 0$.

n INTEGER. The number of columns of the matrix A .
 $n \geq 0$.

α, β REAL for slaset
 DOUBLE PRECISION for dlaset
 COMPLEX for claset
 DOUBLE COMPLEX for zlaset.
 The constants to which the off-diagonal and diagonal elements are to be set, respectively.

a REAL for slaset
 DOUBLE PRECISION for dlaset
 COMPLEX for claset
 DOUBLE COMPLEX for zlaset.
 Array, DIMENSION (lda, n).
 The array a contains the m -by- n matrix A .

lda INTEGER. The leading dimension of the array a .
 $lda \geq \max(1, m)$.

Output Parameters

a On exit, the leading m -by- n submatrix of A is set as follows:
 if $uplo = 'U'$, $A_{ij} = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$,
 if $uplo = 'L'$, $A_{ij} = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$,
 otherwise, $A_{ij} = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, i \neq j$,
 and, for all $uplo$, $A_{ij} = \beta, 1 \leq i \leq \min(m, n)$.

?lasq1

Computes the singular values of a real square bidiagonal matrix. Used by ?bdsqr.

Syntax

```
call slasq1( n, d, e, work, info )
call dlasq1( n, d, e, work, info )
```

Include Files

- mkl.fi

Description

The routine `?lasq1` computes the singular values of a real n -by- n bidiagonal matrix Z with diagonal d and off-diagonal e . The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

Input Parameters

n	INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
d	REAL for <code>slasq1</code> DOUBLE PRECISION for <code>dlasq1</code> . Array, DIMENSION (n). On entry, d contains the diagonal elements of the bidiagonal matrix whose SVD is desired.
e	REAL for <code>slasq1</code> DOUBLE PRECISION for <code>dlasq1</code> . Array, DIMENSION (n). On entry, elements $e(1:n-1)$ contain the off-diagonal elements of the bidiagonal matrix whose SVD is desired.
$work$	REAL for <code>slasq1</code> DOUBLE PRECISION for <code>dlasq1</code> . Workspace array, DIMENSION ($4n$).

Output Parameters

d	On normal exit, d contains the singular values in decreasing order.
e	On exit, e is overwritten.
$info$	INTEGER. = 0: successful exit; < 0: if $info = -i$, the i -th argument had an illegal value; > 0: the algorithm failed: = 1, a split was marked by a positive value in e ; = 2, current block of Z not diagonalized after $100n$ iterations (in inner while loop) - on exit the current contents of d and e represent a matrix with the same singular values as the matrix with which <code>?lasq1</code> was originally called, and which the calling subroutine could use to finish the computation, or even feed back into <code>?lasq1</code> ; = 3, termination criterion of outer while loop not met (program created more than n unreduced blocks).

?lasq2

Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the quotient difference array z to high relative accuracy.

Used by ?bdsqr and ?stegr.

Syntax

```
call slasq2( n, z, info )
```

```
call dlasq2( n, z, info )
```

Include Files

- mkl.fi

Description

The routine ?lasq2 computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the quotient difference array z to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of z to the tridiagonal matrix, let L be a unit lower bidiagonal matrix with subdiagonals $z(2,4,6,\dots)$ and let U be an upper bidiagonal matrix with 1's above and diagonal $z(1,3,5,\dots)$. The tridiagonal is LU or, if you prefer, the symmetric tridiagonal to which it is similar.

Input Parameters

n INTEGER. The number of rows and columns in the matrix. $n \geq 0$.

z REAL for slasq2
DOUBLE PRECISION for dlasq2.
Array, DIMENSION (4 * n).
On entry, z holds the quotient difference array.

Output Parameters

z On exit, entries 1 to n hold the eigenvalues in decreasing order, $z(2n+1)$ holds the trace, and $z(2n+2)$ holds the sum of the eigenvalues. If $n > 2$, then $z(2n+3)$ holds the iteration count, $z(2n+4)$ holds ndivs/n^2 , and $z(2n+5)$ holds the percentage of shifts that failed.

$info$ INTEGER.
= 0: successful exit;
< 0: if the i -th argument is a scalar and had an illegal value, then $info = -i$, if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100 + j)$;
> 0: the algorithm failed:
= 1, a split was marked by a positive value in e ;
= 2, current block of z not diagonalized after $100*n$ iterations (in inner while loop) - On exit z holds a quotient difference array with the same eigenvalues as the z array on entry;

= 3, termination criterion of outer while loop not met (program created more than n unreduced blocks).

Application Notes

The routine `?lasq2` defines a logical variable, `ieee`, which is `.TRUE.` on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs, and `.FALSE.` otherwise. This variable is passed to `?lasq3`.

?lasq3

Checks for deflation, computes a shift and calls dqds.
Used by ?bdsqr.

Syntax

```
call slasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee, ttype,
dmin1, dmin2, dn, dn1, dn2, g, tau )
```

```
call dlasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee, ttype,
dmin1, dmin2, dn, dn1, dn2, g, tau )
```

Include Files

- `mk1.fi`

Description

The routine `?lasq3` checks for deflation, computes a shift `tau`, and calls `dqds`. In case of failure, it changes shifts, and tries again until output is positive.

Input Parameters

<code>i0</code>	INTEGER. First index.
<code>n0</code>	INTEGER. Last index.
<code>z</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Array, DIMENSION (4n). <code>z</code> holds the <code>qd</code> array.
<code>pp</code>	INTEGER. <code>pp=0</code> for ping, <code>pp=1</code> for pong. <code>pp=2</code> indicates that flipping was applied to the <code>Z</code> array and that the initial tests for deflation should not be performed.
<code>desig</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Lower order part of <code>sigma</code> .
<code>qmax</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Maximum value of <code>q</code> .
<code>ieee</code>	LOGICAL.

Flag for `ieee` or non-`ieee` arithmetic (passed to `?lasq5`).

`ttype`

INTEGER.

Shift type.

`dmin1, dmin2, dn, dn1, dn2, g,` REAL for `slasq3`

`tau`

DOUBLE PRECISION for `dlasq3`.

These scalars are passed as arguments in order to save their values between calls to `?lasq3`.

Output Parameters

`dmin`

REAL for `slasq3`

DOUBLE PRECISION for `dlasq3`.

Minimum value of d .

`pp`

INTEGER. $pp=0$ for ping, $pp=1$ for pong. $pp=2$ indicates that flipping was applied to the Z array and that the initial tests for deflation should not be performed.

`sigma`

REAL for `slasq3`

DOUBLE PRECISION for `dlasq3`.

Sum of shifts used in the current segment.

`desig`

Lower order part of σ .

`nfail`

INTEGER. Number of times shift was too big.

`iter`

INTEGER. Number of iterations.

`ndiv`

INTEGER. Number of divisions.

`ttype`

INTEGER.

Shift type.

`dmin1, dmin2, dn, dn1, dn2, g,` REAL for `slasq3`

`tau`

DOUBLE PRECISION for `dlasq3`.

These scalars are passed as arguments in order to save their values between calls to `?lasq3`.

?lasq4

Computes an approximation to the smallest eigenvalue using values of d from the previous transform. Used by `?bdsqr`.

Syntax

call `slasq4(i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype, g)`

call `dlasq4(i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype, g)`

Include Files

- `mkl.fi`

Description

The routine computes an approximation *tau* to the smallest eigenvalue using values of *d* from the previous transform.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of eigtest.
<i>dmin</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Contains <i>d</i> (<i>n</i>).
<i>dn1</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Contains <i>d</i> (<i>n</i> -1).
<i>dn2</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Contains <i>d</i> (<i>n</i> -2).
<i>g</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . A scalar passed as an argument in order to save its value between calls to ? <code>lasq4</code> .

Output Parameters

<i>tau</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Shift.
<i>ttype</i>	INTEGER. Shift type.
<i>g</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. A scalar passed as an argument in order to save its value between calls to ?lasq4.

?lasq5

Computes one dqds transform in ping-pong form.

Used by ?bdsqr and ?stegr.

Syntax

```
call slasq5( i0, n0, z, pp, tau, sigma, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee,
eps )
```

```
call dlasq5( i0, n0, z, pp, tau, sigma, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee,
eps )
```

Include Files

- mkl.fi

Description

The routine computes one dqds transform in ping-pong form: one version for ieee machines, another for non-ieee machines.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the qd array. <i>emin</i> is stored in <i>z</i> (4* <i>n0</i>) to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>tau</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. This is the shift.

<i>sigma</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. This is the accumulated shift up to the current point.
<i>ieee</i>	LOGICAL. Flag for IEEE or non-IEEE arithmetic.
<i>eps</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. This is the value of epsilon used.

Output Parameters

<i>dmin</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of d .
<i>dmin1</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of d , excluding $d(n0)$.
<i>dmin2</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of d , excluding $d(n0)$ and $d(n0-1)$.
<i>dn</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Contains $d(n0)$, the last value of d .
<i>dnm1</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Contains $d(n0-1)$.
<i>dnm2</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Contains $d(n0-2)$.

?lasq6

Computes one dqd transform in ping-pong form. Used by ?bdsqr and ?stegr.

Syntax

```
call slasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
call dlasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
```

Include Files

- mkl.fi

Description

The routine `?lasq6` computes one *dqd* (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Array, DIMENSION (4 <i>n</i>). <i>Z</i> holds the qd array. <i>emin</i> is stored in <i>z</i> (4* <i>n0</i>) to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.

Output Parameters

<i>dmin</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Contains <i>d</i> (<i>n0</i>), the last value of <i>d</i> .
<i>dnm1</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Contains <i>d</i> (<i>n0</i> -1).
<i>dnm2</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Contains <i>d</i> (<i>n0</i> -2).

?lasr

Applies a sequence of plane rotations to a general rectangular matrix.

Syntax

```
call slasr( side, pivot, direct, m, n, c, s, a, lda )
call dlasr( side, pivot, direct, m, n, c, s, a, lda )
call clasr( side, pivot, direct, m, n, c, s, a, lda )
```

$$P(k) = \begin{bmatrix} c(k) & & & s(k) & & \\ & 1 & & & & \\ & & \dots & & & \\ & & & 1 & & \\ -s(k) & & & & c(k) & \\ & & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and $k+1$.

Similarly, when *pivot* = 'B' (Bottom pivot), the rotation is performed for the plane (k, z) , giving $P(k)$ the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & & s(k) \\ & & & & 1 & \\ & & & & & \dots \\ & & & & & & 1 \\ & & -s(k) & & & & c(k) \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and z . The rotations are performed without ever forming $P(k)$ explicitly.

Input Parameters

side

CHARACTER*1. Specifies whether the plane rotation matrix P is applied to A on the left or the right.

= 'L': left, compute $A := P * A$

= 'R': right, compute $A := A * P$

direct

CHARACTER*1. Specifies whether P is a forward or backward sequence of plane rotations.

= 'F': forward, $P = P(z-1) * \dots * P(2) * P(1)$

= 'B': backward, $P = P(1) * P(2) * \dots * P(z-1)$

<i>pivot</i>	<p>CHARACTER*1. Specifies the plane for which $P(k)$ is a plane rotation matrix.</p> <p>= 'V': Variable pivot, the plane $(k, k+1)$</p> <p>= 'T': Top pivot, the plane $(1, k+1)$</p> <p>= 'B': Bottom pivot, the plane (k, z)</p>
<i>m</i>	<p>INTEGER. The number of rows of the matrix A.</p> <p>If $m \leq 1$, an immediate return is effected.</p>
<i>n</i>	<p>INTEGER. The number of columns of the matrix A.</p> <p>If $n \leq 1$, an immediate return is effected.</p>
<i>c, s</i>	<p>REAL for slasr/clasr</p> <p>DOUBLE PRECISION for dlasr/zlasr.</p> <p>Arrays, DIMENSION</p> <p>$(m-1)$ if <i>side</i> = 'L',</p> <p>$(n-1)$ if <i>side</i> = 'R' .</p> <p>$c(k)$ and $s(k)$ contain the cosine and sine of the plane rotations respectively that define the 2-by-2 plane rotation part $(R(k))$ of the $P(k)$ matrix as described above in <i>Description</i>.</p>
<i>a</i>	<p>REAL for slasr</p> <p>DOUBLE PRECISION for dlasr</p> <p>COMPLEX for clasr</p> <p>DOUBLE COMPLEX for zlasr.</p> <p>Array, DIMENSION (lda, n).</p> <p>The m-by-n matrix A.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array a.</p> <p>$lda \geq \max(1, m)$.</p>

Output Parameters

<i>a</i>	On exit, A is overwritten by P^*A if <i>side</i> = 'R', or by A^*P if <i>side</i> = 'L'.
----------	--

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

call slasrt(*id, n, d, info*)

call dlasrt(*id, n, d, info*)

Include Files

- mkl.fi

Description

The routine `?lasrt` sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `stack` limits n to about 2^{32} .

Input Parameters

The data types are given for the Fortran interface.

id	CHARACTER*1. ($d(1) \leq \dots \leq d(n)$) or into decreasing order ($d(1) \geq \dots \geq d(n)$), depending on id .
n	INTEGER. The length of the array d .
d	REAL for <code>slasrt</code> DOUBLE PRECISION for <code>dlasrt</code> . On entry, the array to be sorted.

Output Parameters

d	On exit, d has been sorted into increasing order ($d[0] \leq d[1] \leq \dots \leq d[n-1]$) or into decreasing order ($d[0] \geq d[1] \geq \dots \geq d[n-1]$), depending on id .
$info$	INTEGER. If $info = 0$, the execution is successful. If $info < 0$, the i -th parameter had an illegal value.

?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call slasq( n, x, incx, scale, sumsq )
call dlassq( n, x, incx, scale, sumsq )
call classq( n, x, incx, scale, sumsq )
call zlassq( n, x, incx, scale, sumsq )
```

Include Files

- `mk1.fi`

Description

The real routines `slasq/dlassq` return the values scl and $smsq$ such that

$$scl^2 * smsq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = x(1 + (i - 1) incx)$.

The value of $sumsq$ is assumed to be non-negative and scl returns the value

$$scl = \max(scale, abs(x(i))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *ssq* are overwritten on *scale* and *sumsq*, respectively.

The complex routines *classq/zlassq* return the values *scl* and *ssq* such that

$$scl^2 * ssq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{abs}(x(1 + (i - 1) * incx))$.

The value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy $1.0 \leq ssq \leq sumsq + 2n$

scale is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{aimag}(x(i))))).$$

Values *scale* and *sumsq* must be supplied in *scale* and *sumsq*, and *scl* and *ssq* are overwritten on *scale* and *sumsq*, respectively.

All routines *?lassq* make only one pass through the vector *x*.

Input Parameters

<i>n</i>	INTEGER. The number of elements to be used from the vector <i>x</i> .
<i>x</i>	REAL for <i>slassq</i> DOUBLE PRECISION for <i>dlassq</i> COMPLEX for <i>classq</i> DOUBLE COMPLEX for <i>zlassq</i> . The vector for which a scaled sum of squares is computed: $x(i) = x(1 + (i-1) * incx), 1 \leq i \leq n$.
<i>incx</i>	INTEGER. The increment between successive values of the vector <i>x</i> . <i>incx</i> > 0.
<i>scale</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	For real flavors: On exit, <i>sumsq</i> is overwritten with the value <i>ssq</i> in the equation above. For complex flavors: On exit, <i>sumsq</i> is overwritten with the value <i>ssq</i> in the equation above.

?lasv2

Computes the singular value decomposition of a 2-by-2 triangular matrix.

Syntax

```
call slasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
```

```
call dlasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
```

Include Files

- `mkl.fi`

Description

The routine `?lasv2` computes the singular value decomposition of a 2-by-2 triangular matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, `abs(ssmax)` is the larger singular value, `abs(ssmin)` is the smaller singular value, and `(csl,snl)` and `(csr,snr)` are the left and right singular vectors for `abs(ssmax)`, giving the decomposition

$$\begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} f & g \\ 0 & h \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix} = \begin{bmatrix} ssmax & 0 \\ 0 & ssmin \end{bmatrix}$$

Input Parameters

`f, g, h` REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.

Output Parameters

`ssmin, ssmax` REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
`abs(ssmin)` and `abs(ssmax)` is the smaller and the larger singular value, respectively.

`snl, csl` REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.
The vector `(csl, snl)` is a unit left singular vector for the singular value `abs(ssmax)`.

`snr, csr` REAL for `slasv2`
DOUBLE PRECISION for `dlasv2`.

The vector (*csr*, *snr*) is a unit right singular vector for the singular value `abs(ssmax)`.

Application Notes

Any input parameter may be aliased with any output parameter.

Barring over/underflow and assuming a guard digit in subtraction, all output quantities are correct to within a few units in the last place (ulps).

In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call slaswp( n, a, lda, k1, k2, ipiv, incx )
call dlaswp( n, a, lda, k1, k2, ipiv, incx )
call claswp( n, a, lda, k1, k2, ipiv, incx )
call zlaswp( n, a, lda, k1, k2, ipiv, incx )
```

Include Files

- `mkl.fi`

Description

The routine performs a series of row interchanges on the matrix *A*. One row interchange is initiated for each of rows *k1* through *k2* of *A*.

Input Parameters

The data types are given for the Fortran interface.

<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> .
<i>a</i>	REAL for <code>slaswp</code> DOUBLE PRECISION for <code>dlaswp</code> COMPLEX for <code>claswp</code> DOUBLE COMPLEX for <code>zlaswp</code> . Array, size <i>lda</i> by <i>n</i> . Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> .
<i>k1</i>	INTEGER. The first element of <i>ipiv</i> for which a row interchange will be done.

<i>k2</i>	INTEGER. The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	INTEGER. Array, size $k1 + (k2 - k1) * incx $. The vector of pivot indices. Only the elements in positions <i>k1</i> through <i>k2</i> of <i>ipiv</i> are accessed. $ipiv(k) = l$ implies rows <i>k</i> and <i>l</i> are to be interchanged.
<i>incx</i>	INTEGER. The increment between successive values of <i>ipiv</i> . If <i>ipiv</i> is negative, the pivots are applied in reverse order.

Output Parameters

<i>a</i>	On exit, the permuted matrix.
----------	-------------------------------

?slasy2

Solves the Sylvester matrix equation where the matrices are of order 1 or 2.

Syntax

```
call slasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale, x, ldx,
xnorm, info )
```

```
call dlasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale, x, ldx,
xnorm, info )
```

Include Files

- mkl.fi

Description

The routine solves for the *n1*-by-*n2* matrix *X*, $1 \leq n1, n2 \leq 2$, in

$$\text{op}(TL) * X + \text{isgn} * X * \text{op}(TR) = \text{scale} * B,$$

where

TL is *n1*-by-*n1*,

TR is *n2*-by-*n2*,

B is *n1*-by-*n2*,

and $\text{isgn} = 1$ or -1 . $\text{op}(T) = T$ or T^T , where T^T denotes the transpose of *T*.

Input Parameters

<i>ltranl</i>	LOGICAL. On entry, <i>ltranl</i> specifies the $\text{op}(TL)$: = .FALSE., $\text{op}(TL) = TL$, = .TRUE., $\text{op}(TL) = (TL)^T$.
<i>ltranr</i>	LOGICAL.

On entry, *ltranr* specifies the $\text{op}(TR)$:

= .FALSE., $\text{op}(TR) = TR$,
 = .TRUE., $\text{op}(TR) = (TR)^T$.

isgn INTEGER. On entry, *isgn* specifies the sign of the equation as described before. *isgn* may only be 1 or -1.

n1 INTEGER. On entry, *n1* specifies the order of matrix *TL*.
n1 may only be 0, 1 or 2.

n2 INTEGER. On entry, *n2* specifies the order of matrix *TR*.
n2 may only be 0, 1 or 2.

tl REAL for slasy2
 DOUBLE PRECISION for dlasy2.
 Array, DIMENSION (*ldtl*,2).
 On entry, *tl* contains an *n1*-by-*n1* matrix *TL*.

ldtl INTEGER. The leading dimension of the matrix *TL*.
ldtl $\geq \max(1, n1)$.

tr REAL for slasy2
 DOUBLE PRECISION for dlasy2.
 Array, DIMENSION (*ldtr*,2). On entry, *tr* contains an *n2*-by-*n2* matrix *TR*.

ldtr INTEGER. The leading dimension of the matrix *TR*.
ldtr $\geq \max(1, n2)$.

b REAL for slasy2
 DOUBLE PRECISION for dlasy2.
 Array, DIMENSION (*ldb*,2). On entry, the *n1*-by-*n2* matrix *B* contains the right-hand side of the equation.

ldb INTEGER. The leading dimension of the matrix *B*.
ldb $\geq \max(1, n1)$.

ldx INTEGER. The leading dimension of the output matrix *X*.
ldx $\geq \max(1, n1)$.

Output Parameters

scale REAL for slasy2
 DOUBLE PRECISION for dlasy2.
 On exit, *scale* contains the scale factor.
scale is chosen less than or equal to 1 to prevent the solution overflowing.

<code>x</code>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlasy2</code> . Array, DIMENSION (<code>ldx</code> ,2). On exit, <code>x</code> contains the $n1$ -by- $n2$ solution.
<code>xnorm</code>	REAL for <code>slasy2</code> DOUBLE PRECISION for <code>dlasy2</code> . On exit, <code>xnorm</code> is the infinity-norm of the solution.
<code>info</code>	INTEGER. On exit, <code>info</code> is set to 0: successful exit. 1: <i>TL</i> and <i>TR</i> have too close eigenvalues, so <i>TL</i> or <i>TR</i> is perturbed to get a nonsingular equation.

NOTE

For higher speed, this routine does not check the inputs for errors.

?lasyf

Computes a partial factorization of a symmetric matrix, using the diagonal pivoting method.

Syntax

```
call slasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- `mkl.fi`

Description

The routine `?lasyf` computes a partial factorization of a symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

If `uplo = 'U'`:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}^T & U_{22}^T \end{bmatrix}$$

`uplo = 'L'`

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}^T & L_{21}^T \\ 0 & I \end{bmatrix}$$

where the order of D is at most nb .

The actual order is returned in the argument `kb`, and is either nb or $nb-1$, or n if $n \leq nb$.

This is an auxiliary routine called by `?sytrf`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if `uplo = 'U'`) or A_{22} (if `uplo = 'L'`).

Input Parameters

<code>uplo</code>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular</p>
<code>n</code>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p>
<code>nb</code>	<p>INTEGER. The maximum number of columns of the matrix A that should be factored. <code>nb</code> should be at least 2 to allow for 2-by-2 pivot blocks.</p>
<code>a</code>	<p>REAL for <code>slasyf</code></p> <p>DOUBLE PRECISION for <code>dlasyf</code></p> <p>COMPLEX for <code>clasyf</code></p> <p>DOUBLE COMPLEX for <code>zlasyf</code>.</p> <p>Array, DIMENSION (<code>lda</code>, <code>n</code>). If <code>uplo = 'U'</code>, the leading n-by-n upper triangular part of <code>a</code> contains the upper triangular part of the matrix A, and the strictly lower triangular part of <code>a</code> is not referenced. If <code>uplo = 'L'</code>, the leading n-by-n lower triangular part of <code>a</code> contains the lower triangular part of the matrix A, and the strictly upper triangular part of <code>a</code> is not referenced.</p>
<code>lda</code>	<p>INTEGER. The leading dimension of the array <code>a</code>. $lda \geq \max(1, n)$.</p>
<code>w</code>	<p>REAL for <code>slasyf</code></p> <p>DOUBLE PRECISION for <code>dlasyf</code></p> <p>COMPLEX for <code>clasyf</code></p> <p>DOUBLE COMPLEX for <code>zlasyf</code>.</p> <p>Workspace array, DIMENSION (<code>ldw</code>, <code>nb</code>).</p>
<code>ldw</code>	<p>INTEGER. The leading dimension of the array <code>w</code>. $ldw \geq \max(1, nb)$.</p>

Output Parameters

<code>kb</code>	<p>INTEGER. The number of columns of A that were actually factored <code>kb</code> is either <code>nb-1</code> or <code>nb</code>, or <code>n</code> if $n \leq nb$.</p>
<code>a</code>	<p>On exit, <code>a</code> contains details of the partial factorization.</p>
<code>ipiv</code>	<p>INTEGER. Array, DIMENSION (<code>n</code>). Details of the interchanges and the block structure of D.</p> <p>If <code>uplo = 'U'</code>, only the last <code>kb</code> elements of <code>ipiv</code> are set;</p> <p>if <code>uplo = 'L'</code>, only the first <code>kb</code> elements are set.</p>

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lasyf_rook

Computes a partial factorization of a complex symmetric matrix, using the bounded Bunch-Kaufman diagonal pivoting method.

Syntax

```
call slasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- mkl.fi

Description

The routine `?lasyf_rook` computes a partial factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}^T & U_{22}^T \end{bmatrix}$$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}^T & L_{21}^T \\ 0 & I \end{bmatrix}$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

This is an auxiliary routine called by `?sytrf_rook`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored:</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>nb</i>	<p>INTEGER. The maximum number of columns of the matrix <i>A</i> that should be factored. <i>nb</i> should be at least 2 to allow for 2-by-2 pivot blocks.</p>
<i>a</i>	<p>REAL for slasyf_rook</p> <p>DOUBLE PRECISION for dlasyf_rook</p> <p>COMPLEX for clasyf_rook</p> <p>DOUBLE COMPLEX for zlasyf_rook.</p> <p>Array, DIMENSION (<i>lda</i>, <i>n</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>a</i> is not referenced.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(1, n)$.</p>
<i>w</i>	<p>REAL for slasyf_rook</p> <p>DOUBLE PRECISION for dlasyf_rook</p> <p>COMPLEX for clasyf_rook</p> <p>DOUBLE COMPLEX for zlasyf_rook.</p> <p>Workspace array, DIMENSION (<i>ldw</i>, <i>nb</i>).</p>
<i>ldw</i>	<p>INTEGER. The leading dimension of the array <i>w</i>. $ldw \geq \max(1, n)$.</p>

Output Parameters

<i>kb</i>	<p>INTEGER. The number of columns of <i>A</i> that were actually factored <i>kb</i> is either <i>nb</i>-1 or <i>nb</i>, or <i>n</i> if $n \leq nb$.</p>
<i>a</i>	<p>On exit, <i>a</i> contains details of the partial factorization.</p>
<i>ipiv</i>	<p>INTEGER. Array, DIMENSION (<i>n</i>). Details of the interchanges and the block structure of <i>D</i>.</p> <p>If <i>uplo</i> = 'U', only the last <i>kb</i> elements of <i>ipiv</i> are set;</p> <p>if <i>uplo</i> = 'L', only the first <i>kb</i> elements are set.</p> <p>If $ipiv(k) > 0$, then rows and columns <i>k</i> and <i>ipiv</i>(<i>k</i>) were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.</p>

If $uplo = 'U'$ and $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lahef

Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.

Syntax

```
call clahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

```
call zlahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- mkl.fi

Description

The routine ?lahef computes a partial factorization of a complex Hermitian matrix A , using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

If $uplo = 'U'$:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}^H & U_{22}^H \end{bmatrix}$$

If $uplo = 'L'$:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}^H & L_{21}^H \\ 0 & I \end{bmatrix}$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

Note that U^H denotes the conjugate transpose of U .

This is an auxiliary routine called by ?hetrf. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored:</p> <p>= 'U': upper triangular</p> <p>= 'L': lower triangular</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>nb</i>	<p>INTEGER. The maximum number of columns of the matrix <i>A</i> that should be factored. <i>nb</i> should be at least 2 to allow for 2-by-2 pivot blocks.</p>
<i>a</i>	<p>COMPLEX for <code>clahef</code></p> <p>DOUBLE COMPLEX for <code>zlahef</code>.</p> <p>Array, DIMENSION (<i>lda</i>, <i>n</i>).</p> <p>On entry, the Hermitian matrix <i>A</i>.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>A</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>A</i> is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>A</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>A</i> is not referenced.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(1, n)$.</p>
<i>w</i>	<p>COMPLEX for <code>clahef</code></p> <p>DOUBLE COMPLEX for <code>zlahef</code>.</p> <p>Workspace array, DIMENSION (<i>ldw</i>, <i>nb</i>).</p>
<i>ldw</i>	<p>INTEGER. The leading dimension of the array <i>w</i>. $ldw \geq \max(1, n)$.</p>

Output Parameters

<i>kb</i>	<p>INTEGER. The number of columns of <i>A</i> that were actually factored <i>kb</i> is either <i>nb</i>-1 or <i>nb</i>, or <i>n</i> if $n \leq nb$.</p>
<i>a</i>	<p>On exit, <i>A</i> contains details of the partial factorization.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>). Details of the interchanges and the block structure of <i>D</i>.</p> <p>If <i>uplo</i> = 'U', only the last <i>kb</i> elements of <i>ipiv</i> are set;</p> <p>if <i>uplo</i> = 'L', only the first <i>kb</i> elements are set.</p> <p>If <i>ipiv</i>(<i>k</i>) > 0, then rows and columns <i>k</i> and <i>ipiv</i>(<i>k</i>) are interchanged and <i>D</i>(<i>k</i>, <i>k</i>) is a 1-by-1 diagonal block.</p>

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ are interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?lahef_rook

Computes a partial factorization of a complex Hermitian indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method.

Syntax

```
call clahef_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

```
call zlahef_rook( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Include Files

- mkl.fi

Description

The routine `?lahef_rook` computes a partial factorization of a complex Hermitian matrix A , using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The partial factorization has the form:

If $uplo = 'U'$:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{22} \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}^H & U_{22}^H \end{bmatrix}$$

If $uplo = 'L'$:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{11}^H & L_{21}^H \\ 0 & I \end{bmatrix}$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

Note that U^H denotes the conjugate transpose of U .

This is an auxiliary routine called by `?hetrf_rook`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored:</p> <p>= 'U': upper triangular</p> <p>= 'L': lower triangular</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>nb</i>	<p>INTEGER. The maximum number of columns of the matrix <i>A</i> that should be factored. <i>nb</i> should be at least 2 to allow for 2-by-2 pivot blocks.</p>
<i>a</i>	<p>COMPLEX for <code>clahef_rook</code></p> <p>DOUBLE COMPLEX for <code>zlahef_rook</code>.</p> <p>Array, DIMENSION (<i>lda</i>, <i>n</i>).</p> <p>On entry, the Hermitian matrix <i>A</i>.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>A</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>A</i> is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>A</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>A</i> is not referenced.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(1, n)$.</p>
<i>w</i>	<p>COMPLEX for <code>clahef_rook</code></p> <p>DOUBLE COMPLEX for <code>zlahef_rook</code>.</p> <p>Workspace array, DIMENSION (<i>ldw</i>, <i>nb</i>).</p>
<i>ldw</i>	<p>INTEGER. The leading dimension of the array <i>w</i>. $ldw \geq \max(1, n)$.</p>

Output Parameters

<i>kb</i>	<p>INTEGER. The number of columns of <i>A</i> that were actually factored <i>kb</i> is either <i>nb</i>-1 or <i>nb</i>, or <i>n</i> if $n \leq nb$.</p>
<i>a</i>	<p>On exit, <i>A</i> contains details of the partial factorization.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>). Details of the interchanges and the block structure of <i>D</i>.</p> <p>If <i>uplo</i> = 'U', only the last <i>kb</i> elements of <i>ipiv</i> are set;</p> <p>if <i>uplo</i> = 'L', only the first <i>kb</i> elements are set.</p> <p>If <i>ipiv</i>(<i>k</i>) > 0, then rows and columns <i>k</i> and <i>ipiv</i>(<i>k</i>) are interchanged and <i>D</i>(<i>k</i>, <i>k</i>) is a 1-by-1 diagonal block.</p>

If $uplo = 'U'$ and $ipiv(k) < 0$ and $ipiv(k-1) < 0$, then rows and columns k and $-ipiv(k)$ are interchanged, rows and columns $k-1$ and $-ipiv(k-1)$ are interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) < 0$ and $ipiv(k+1) < 0$, then rows and columns k and $-ipiv(k)$ are interchanged, rows and columns $k+1$ and $-ipiv(k+1)$ are interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?latbs

Solves a triangular banded system of equations.

Syntax

call slatbs(*uplo*, *trans*, *diag*, *normin*, *n*, *kd*, *ab*, *ldab*, *x*, *scale*, *cnorm*, *info*)

call dlatbs(*uplo*, *trans*, *diag*, *normin*, *n*, *kd*, *ab*, *ldab*, *x*, *scale*, *cnorm*, *info*)

call clatbs(*uplo*, *trans*, *diag*, *normin*, *n*, *kd*, *ab*, *ldab*, *x*, *scale*, *cnorm*, *info*)

call zlatbs(*uplo*, *trans*, *diag*, *normin*, *n*, *kd*, *ab*, *ldab*, *x*, *scale*, *cnorm*, *info*)

Include Files

- mkl.fi

Description

The routine solves one of the triangular systems

$A*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine `?tbsv` is called. If the matrix A is singular ($A(j, j)=0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

uplo

CHARACTER*1.

Specifies whether the matrix A is upper or lower triangular.

= 'U': upper triangular

= 'L': lower triangular

trans

CHARACTER*1.

Specifies the operation applied to A .

= 'N': solve $A*x = s*b$ (no transpose)

= 'T': solve $A^T*x = s*b$ (transpose)

	= 'C': solve $A^H * x = s * b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms is computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>kd</i>	INTEGER. The number of subdiagonals or superdiagonals in the triangular matrix <i>A</i> . $kb \geq 0$.
<i>ab</i>	REAL for slatbs DOUBLE PRECISION for dlatbs COMPLEX for clatbs DOUBLE COMPLEX for zlatbs. Array, DIMENSION (<i>ldab</i> , <i>n</i>). The upper or lower triangular band matrix <i>A</i> , stored in the first <i>kb</i> +1 rows of the array. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . $ldab \geq kb+1$.
<i>x</i>	REAL for slatbs DOUBLE PRECISION for dlatbs COMPLEX for clatbs DOUBLE COMPLEX for zlatbs. Array, DIMENSION (<i>n</i>). On entry, the right hand side <i>b</i> of the triangular system.
<i>cnorm</i>	REAL for slatbs/clatbs DOUBLE PRECISION for dlatbs/zlatbs. Array, DIMENSION (<i>n</i>). If <i>NORMIN</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> (<i>j</i>) contains the norm of the off-diagonal part of the <i>j</i> -th column of <i>A</i> .

If $trans = 'N'$, $cnorm(j)$ must be greater than or equal to the infinity-norm, and if $trans = 'T'$ or $'C'$, $cnorm(j)$ must be greater than or equal to the 1-norm.

Output Parameters

<i>scale</i>	<p>REAL for slatbs/clatbs</p> <p>DOUBLE PRECISION for dlatbs/zlatbs.</p> <p>The scaling factor s for the triangular system as described above. If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $Ax = 0$.</p>
<i>cnorm</i>	<p>If $normin = 'N'$, $cnorm$ is an output argument and $cnorm(j)$ returns the 1-norm of the off-diagonal part of the j-th column of A.</p>
<i>info</i>	<p>INTEGER.</p> <p>= 0: successful exit</p> <p>< 0: if $info = -k$, the k-th argument had an illegal value</p>

?latm1

Computes the entries of a matrix as specified.

Syntax

```
call slatm1( mode, cond, irsign, idist, iseed, d, n, info )
call dlatm1( mode, cond, irsign, idist, iseed, d, n, info )
call clatm1( mode, cond, irsign, idist, iseed, d, n, info )
call zlatm1( mode, cond, irsign, idist, iseed, d, n, info )
```

Include Files

- mkl.fi

Description

The ?latm1 routine computes the entries of $D(1..n)$ as specified by *mode*, *cond* and *irsign*. *idist* and *iseed* determine the generation of random numbers.

?latm1 is called by slatmr (for slatm1 and dlatm1), and by clatmr (for clatm1 and zlatm1) to generate random test matrices for LAPACK programs.

Input Parameters

<i>mode</i>	<p>INTEGER. On entry describes how d is to be computed:</p> <p>$mode = 0$ means do not change d.</p> <p>$mode = 1$ sets $d(1) = 1$ and $d(2:n) = 1.0/cond$</p> <p>$mode = 2$ sets $d(1:n-1) = 1$ and $d(n)=1.0/cond$</p> <p>$mode = 3$ sets $d(i)=cond^{*(-(i-1)/(n-1))}$</p> <p>$mode = 4$ sets $d(i)=1 - (i-1)/(n-1)*(1 - 1/cond)$</p>
-------------	---

$mode = 5$ sets d to random numbers in the range $(1/cond, 1)$ such that their logarithms are uniformly distributed.

$mode = 6$ sets d to random numbers from same distribution as the rest of the matrix.

$mode < 0$ has the same meaning as $abs(mode)$, except that the order of the elements of d is reversed.

Thus if $mode$ is positive, d has entries ranging from 1 to $1/cond$, if negative, from $1/cond$ to 1.

cond

REAL for slatml,
DOUBLE PRECISION for dlatml,
REAL for clatml,
DOUBLE PRECISION for zlatml,

On entry, used as described under *mode* above. If used, it must be ≥ 1 .

irsign

INTEGER.

On entry, if *mode* is not -6, 0, or 6, determines sign of entries of d .

If *irsign* = 0, entries of d are unchanged.

If *irsign* = 1, each entry of d is multiplied by a random complex number uniformly distributed with absolute value 1.

idist

INTEGER. Specifies the distribution of the random numbers.

For slatml and dlatml:

= 1: uniform (0,1)

= 2: uniform (-1,1)

= 3: normal (0,1)

For clatml and zlatml:

= 1: real and imaginary parts each uniform (0,1)

= 2: real and imaginary parts each uniform (-1,1)

= 3: real and imaginary parts each normal (0,1)

= 4: complex number uniform in disk(0, 1)

iseed

INTEGER. Array, size (4).

Specifies the seed of the random number generator. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of *iseed*(4) are changed on exit, and can be used in the next call to ?latml to continue the same random number sequence.

d

REAL for slatml,
DOUBLE PRECISION for dlatml,
COMPLEX for clatml,
DOUBLE COMPLEX for zlatml,

Array, size n .

n INTEGER. Number of entries of d .

Output Parameters

$iseed$ On exit, the seed is updated.

d On exit, d is updated, unless $mode = 0$.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -1$, $mode$ is not in range -6 to 6.

If $info = -2$, $mode$ is neither -6, 0 nor 6, and $irsign$ is neither 0 nor 1.

If $info = -3$, $mode$ is neither -6, 0 nor 6 and $cond$ is less than 1.

If $info = -4$, $mode$ equals 6 or -6 and $idist$ is not in range 1 to 4.

If $info = -7$, n is negative.

?latm2

Returns an entry of a random matrix.

Syntax

```
res = slatm2( m, n, i, j, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng, iwork,
sparse )
```

```
res = dlatm2( m, n, i, j, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng, iwork,
sparse )
```

```
res = clatm2( m, n, i, j, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng, iwork,
sparse )
```

```
res = zlatm2( m, n, i, j, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng, iwork,
sparse )
```

Include Files

- mkl.fi

Description

The ?latm2 routine returns entry (i, j) of a random matrix of dimension (m, n) . It is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of ?latm2 differs from ?latm3 in the order in which the random number generator is called to fill in random matrix entries. With ?latm2, the generator is called to fill in the pivoted matrix columnwise. With ?latm2, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, ?latm3 can be used to construct random matrices which differ only in their order of rows and/or columns. ?latm2 is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers).

The matrix whose (i, j) entry is returned is constructed as follows (this routine only computes one entry):

- If i is outside $(1..m)$ or j is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix A with random entries of distribution $idist$.
- Set the diagonal to D .
- Grade the matrix, if desired, from the left (by dl) and/or from the right (by dr or dl) as specified by $igrade$.
- Permute, if desired, the rows and/or columns as specified by $ipvtng$ and $iwork$.
- Band the matrix to have lower bandwidth kl and upper bandwidth ku .
- Set random entries to zero as specified by $sparse$.

Input Parameters

m	INTEGER. Number of rows of the matrix.
n	INTEGER. Number of columns of the matrix.
i	INTEGER. Row of the entry to be returned.
j	INTEGER. Column of the entry to be returned.
kl	INTEGER. Lower bandwidth.
ku	INTEGER. Upper bandwidth.
$idist$	<p>INTEGER. On entry, $idist$ specifies the type of distribution to be used to generate a random matrix .</p> <p>for $slatm2$ and $dlatm2$:</p> <p>= 1: uniform (0,1)</p> <p>= 2: uniform (-1,1)</p> <p>= 3: normal (0,1)</p> <p>for $clatm2$ and $zlatm2$:</p> <p>= 1: real and imaginary parts each uniform (0,1)</p> <p>= 2: real and imaginary parts each uniform (-1,1)</p> <p>= 3: real and imaginary parts each normal (0,1)</p> <p>= 4: complex number uniform in disk (0, 1)</p>
$iseed$	<p>INTEGER. Array, size 4.</p> <p>Seed for the random number generator.</p>
d	<p>REAL for $slatm2$,</p> <p>DOUBLE PRECISION for $dlatm2$,</p> <p>COMPLEX for $clatm2$,</p> <p>DOUBLE COMPLEX for $zlatm2$,</p> <p>Array, size $(\min(i, j))$. Diagonal entries of matrix.</p>
$igrade$	<p>INTEGER. Specifies grading of matrix as follows:</p> <p>= 0: no grading</p> <p>= 1: matrix premultiplied by $\text{diag}(dl)$</p>

= 2: matrix postmultiplied by $\text{diag}(dr)$
 = 3: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$
 = 4: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$
 For `slatm2` and `slatm2`:
 = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$
 For `clatm2` and `zlatm2`:
 = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$
 = 6: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$

dl

REAL for `slatm2`,
 DOUBLE PRECISION for `dlatm2`,
 COMPLEX for `clatm2`,
 DOUBLE COMPLEX for `zlatm2`,
 Array, size (*i* or *j*), as appropriate.
 Left scale factors for grading matrix.

dr

REAL for `slatm2`,
 DOUBLE PRECISION for `dlatm2`,
 COMPLEX for `clatm2`,
 DOUBLE COMPLEX for `zlatm2`,
 Array, size (*i* or *j*), as appropriate.
 Right scale factors for grading matrix.

ipvtng

INTEGER. On entry specifies pivoting permutations as follows:
 = 0: none
 = 1: row pivoting
 = 2: column pivoting
 = 3: full pivoting, i.e., on both sides

iwork

INTEGER.
 Array, size (*i* or *j*), as appropriate. This array specifies the permutation used. The row (or column) in position *k* was originally in position `iwork(k)`. This differs from `iwork` for `?latm3`.

sparse

REAL for `slatm2`,
 DOUBLE PRECISION for `dlatm2`,
 REAL for `clatm2`,
 DOUBLE PRECISION for `zlatm2`,

Specifies the sparsity of the matrix. If sparse matrix is to be generated, *sparse* should lie between 0 and 1. A uniform (0, 1) random number *x* is generated and compared to *sparse*. If *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

Output Parameters

<i>iseed</i>	INTEGER. On exit, the seed is updated.
<i>res</i>	REAL for slatm2, DOUBLE PRECISION for dlatm2, COMPLEX for clatm2, DOUBLE COMPLEX for zlatm2, Entry of a random matrix.

?latm3

Returns set entry of a random matrix.

Syntax

```
res = slatm3( m, n, i, j, isub, jsub, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng,
iwork, sparse )

res = dlatm3( m, n, i, j, isub, jsub, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng,
iwork, sparse )

res = clatm3( m, n, i, j, isub, jsub, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng,
iwork, sparse )

res = zlatm3( m, n, i, j, isub, jsub, kl, ku, idist, iseed, d, igrade, dl, dr, ipvtng,
iwork, sparse )
```

Include Files

- mkl.fi

Description

The ?latm3 routine returns the (*isub*, *jsub*) entry of a random matrix of dimension (*m*, *n*) described by the other parameters. (*isub*, *jsub*) is the final position of the (*i*, *j*) entry after pivoting according to *ipvtng* and *iwork*. ?latm3 is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of ?latm3 differs from ?latm2 in the order in which the random number generator is called to fill in random matrix entries. With ?latm2, the generator is called to fill in the pivoted matrix columnwise. With ?latm3, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, ?latm3 can be used to construct random matrices which differ only in their order of rows and/or columns. ?latm2 is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers in different orders for different pivot orders).

The matrix whose (*isub*, *jsub*) entry is returned is constructed as follows (this routine only computes one entry):

- If *isub* is outside $(1..m)$ or *jsub* is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix *A* with random entries of distribution *idist*.
- Set the diagonal to *D*.
- Grade the matrix, if desired, from the left (by *dl*) and/or from the right (by *dr* or *dl*) as specified by *igrade*.
- Permute, if desired, the rows and/or columns as specified by *ipvtng* and *iwork*.
- Band the matrix to have lower bandwidth *kl* and upper bandwidth *ku*.
- Set random entries to zero as specified by *sparse*.

Input Parameters

<i>m</i>	INTEGER. Number of rows of matrix.
<i>n</i>	INTEGER. Number of columns of matrix.
<i>i</i>	INTEGER. Row of unpivoted entry to be returned.
<i>j</i>	INTEGER. Column of unpivoted entry to be returned.
<i>isub</i>	INTEGER. Row of pivoted entry to be returned.
<i>jsub</i>	INTEGER. Column of pivoted entry to be returned.
<i>kl</i>	INTEGER. Lower bandwidth.
<i>ku</i>	INTEGER. Upper bandwidth.
<i>idist</i>	<p>INTEGER. On entry, <i>idist</i> specifies the type of distribution to be used to generate a random matrix.</p> <p>for <i>slatm2</i> and <i>dlatm2</i>:</p> <p>= 1: uniform (0,1)</p> <p>= 2: uniform (-1,1)</p> <p>= 3: normal (0,1)</p> <p>for <i>clatm2</i> and <i>zlatm2</i>:</p> <p>= 1: real and imaginary parts each uniform (0,1)</p> <p>= 2: real and imaginary parts each uniform (-1,1)</p> <p>= 3: real and imaginary parts each normal (0,1)</p> <p>= 4: complex number uniform in disk(0, 1)</p>
<i>iseed</i>	<p>INTEGER. Array, size 4.</p> <p>Seed for random number generator.</p>
<i>d</i>	<p>REAL for <i>slatm3</i>,</p> <p>DOUBLE PRECISION for <i>dlatm3</i>,</p> <p>COMPLEX for <i>clatm3</i>,</p> <p>DOUBLE COMPLEX for <i>zlatm3</i>,</p> <p>Array, size $(\min(i, j))$. Diagonal entries of matrix.</p>

<i>igrade</i>	<p>INTEGER. Specifies grading of matrix as follows:</p> <ul style="list-style-type: none"> = 0: no grading = 1: matrix premultiplied by diag(<i>dl</i>) = 2: matrix postmultiplied by diag(<i>dr</i>) = 3: matrix premultiplied by diag(<i>dl</i>) and postmultiplied by diag(<i>dr</i>) = 4: matrix premultiplied by diag(<i>dl</i>) and postmultiplied by inv(diag(<i>dl</i>)) <p>For <i>slatm2</i> and <i>slatm2</i>:</p> <ul style="list-style-type: none"> = 5: matrix premultiplied by diag(<i>dl</i>) and postmultiplied by diag(<i>dl</i>) <p>For <i>clatm2</i> and <i>zlatm2</i>:</p> <ul style="list-style-type: none"> = 5: matrix premultiplied by diag(<i>dl</i>) and postmultiplied by diag(conjg(<i>dl</i>)) = 6: matrix premultiplied by diag(<i>dl</i>) and postmultiplied by diag(<i>dl</i>)
<i>dl</i>	<p>REAL for <i>slatm3</i>,</p> <p>DOUBLE PRECISION for <i>dlatm3</i>,</p> <p>COMPLEX for <i>clatm3</i>,</p> <p>DOUBLE COMPLEX for <i>zlatm3</i>,</p> <p>Array, size (<i>i</i> or <i>j</i>, as appropriate).</p> <p>Left scale factors for grading matrix.</p>
<i>dr</i>	<p>REAL for <i>slatm3</i>,</p> <p>DOUBLE PRECISION for <i>dlatm3</i>,</p> <p>COMPLEX for <i>clatm3</i>,</p> <p>DOUBLE COMPLEX for <i>zlatm3</i>,</p> <p>Array, size (<i>i</i> or <i>j</i>, as appropriate).</p> <p>Right scale factors for grading matrix.</p>
<i>ipvtng</i>	<p>INTEGER. On entry specifies pivoting permutations as follows:</p> <ul style="list-style-type: none"> If <i>ipvtng</i> = 0: none. If <i>ipvtng</i> = 1: row pivoting. If <i>ipvtng</i> = 2: column pivoting. If <i>ipvtng</i> = 3: full pivoting, i.e., on both sides.
<i>sparse</i>	<p>REAL for <i>slatm3</i>,</p> <p>DOUBLE PRECISION for <i>dlatm3</i>,</p> <p>REAL for <i>clatm3</i>,</p> <p>DOUBLE PRECISION for <i>zlatm3</i>,</p>

On entry, specifies the sparsity of the matrix if sparse matrix is to be generated. *sparse* should lie between 0 and 1. A uniform(0, 1) random number *x* is generated and compared to *sparse*; if *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

iwork

INTEGER.

Array, size (*i* or *j*, as appropriate). This array specifies the permutation used. The row (or column) originally in position *k* is in position *iwork*(*k*) after pivoting. This differs from *iwork* for ?latm2.

Output Parameters

isub

On exit, row of pivoted entry is updated.

jsub

On exit, column of pivoted entry is updated.

iseed

On exit, the seed is updated.

res

REAL for slatm3,

DOUBLE PRECISION for dlatm3,

COMPLEX for clatm3,

DOUBLE COMPLEX for zlatm3,

Entry of a random matrix.

?latm5

Generates matrices involved in the Generalized Sylvester equation.

Syntax

```
call slatm5( prtype, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf, r, ldr, l,
ldl, alpha, qblcka, qblckb )
```

```
call dlatm5( prtype, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf, r, ldr, l,
ldl, alpha, qblcka, qblckb )
```

```
call clatm5( prtype, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf, r, ldr, l,
ldl, alpha, qblcka, qblckb )
```

```
call zlatm5( prtype, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf, r, ldr, l,
ldl, alpha, qblcka, qblckb )
```

Description

The ?latm5 routine generates matrices involved in the Generalized Sylvester equation:

$$A * R - L * B = C$$

$$D * R - L * E = F$$

They also satisfy the diagonalization condition:

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} A & -C \\ & B \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} A & \\ & B \end{bmatrix}$$

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} D & -F \\ & E \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} D & \\ & E \end{bmatrix}$$

Input Parameters

prtype

INTEGER. Specifies the type of matrices to generate.

- If *prtype* = 1, *A* and *B* are Jordan blocks, *D* and *E* are identity matrices.

A:

If (*i* == *j*) then $A_{i,j} = 1.0$.

If (*j* == *i* + 1) then $A_{i,j} = -1.0$.

Otherwise $A_{i,j} = 0.0$, *i*, *j* = 1...*m*

B:

If (*i* == *j*) then $B_{i,j} = 1.0 - \alpha$.

If (*j* == *i* + 1) then $B_{i,j} = 1.0$.

Otherwise $B_{i,j} = 0.0$, *i*, *j* = 1...*n*.

D:

If (*i* == *j*) then $D_{i,j} = 1.0$.

Otherwise $D_{i,j} = 0.0$, *i*, *j* = 1...*m*.

E:

If (*i* == *j*) then $E_{i,j} = 1.0$

Otherwise $E_{i,j} = 0.0$, *i*, *j* = 1...*n*.

L = *R* are chosen from [-10...10], which specifies the right hand sides (*C*, *F*).

- If *prtype* = 2 or 3: Triangular and/or quasi- triangular.

A:

If (*i* ≤ *j*) then $A_{i,j} = [-1...1]$.

Otherwise $A_{i,j} = 0.0$, *i*, *j* = 1...*M*.

If (*prtype* = 3) then $A_{k+1,k+1} = A_{k,k}$;

$A_{k+1,k} = [-1...1]$;

$\text{sign}(A_{k,k+1}) = -(\text{sign}(A_{k+1,k}))$.

k = 1, *m* - 1, *qblocka*

B :

If (*i* ≤ *j*) then $B_{i,j} = [-1...1]$.

Otherwise $B_{i,j} = 0.0$, *i*, *j* = 1...*n*.

If (*prtype* = 3) then $B_{k+1,k+1} = B_{k,k}$

$B_{k+1,k} = [-1...1]$

$\text{sign}(B_{k,k+1}) = -(\text{sign}(B_{k+1,k}))$

$k = 1, n - 1, \text{qblckb}.$

D:

If $(i \leq j)$ then $D_{i,j} = [-1 \dots 1].$

Otherwise $D_{i,j} = 0.0, \quad i, j = 1 \dots m.$

E:

If $(i \leq j)$ then $E_{i,j} = [-1 \dots 1].$

Otherwise $E_{i,j} = 0.0, \quad i, j = 1 \dots N.$

L, R are chosen from $[-10 \dots 10]$, which specifies the right hand sides (*C, F*).

- If *prtype* = 4 Full

$A_{i,j} = [-10 \dots 10]$

$D_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots m$

$B_{i,j} = [-10 \dots 10]$

$E_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots n$

$R_{i,j} = [-10 \dots 10]$

$L_{i,j} = [-1 \dots 1] \quad i = 1 \dots m, j = 1 \dots n$

L and *R* specifies the right hand sides (*C, F*).

- If *prtype* = 5 special case common and/or close eigs.

<i>m</i>	INTEGER. Specifies the order of <i>A</i> and <i>D</i> and the number of rows in <i>C, F, R</i> and <i>L</i> .
<i>n</i>	INTEGER. Specifies the order of <i>B</i> and <i>E</i> and the number of columns in <i>C, F, R</i> and <i>L</i> .
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> .
<i>ldc</i>	INTEGER. The leading dimension of <i>c</i> .
<i>ldd</i>	INTEGER. The leading dimension of <i>d</i> .
<i>lde</i>	INTEGER. The leading dimension of <i>e</i> .
<i>ldf</i>	INTEGER. The leading dimension of <i>f</i> .
<i>ldr</i>	INTEGER. The leading dimension of <i>r</i> .
<i>ldl</i>	INTEGER. The leading dimension of <i>l</i> .
<i>alpha</i>	REAL for slatm5, DOUBLE PRECISION for dlatm5, REAL for clatm5, DOUBLE PRECISION for zlatm5,

Parameter used in generating *prtype* = 1 and 5 matrices.

qblcka INTEGER. When *prtype* = 3, specifies the distance between 2-by-2 blocks on the diagonal in *A*. Otherwise, *qblcka* is not referenced. *qblcka* > 1.

qblckb INTEGER. When *prtype* = 3, specifies the distance between 2-by-2 blocks on the diagonal in *B*. Otherwise, *qblckb* is not referenced. *qblckb* > 1.

Output Parameters

a REAL for slatm5,
DOUBLE PRECISION for dlatm5,
COMPLEX for clatm5,
DOUBLE COMPLEX for zlatm5,
Array, size (*lda*, *m*). On exit *a* contains *m*-by-*m* array *A* initialized according to *prtype*.

b REAL for slatm5,
DOUBLE PRECISION for dlatm5,
COMPLEX for clatm5,
DOUBLE COMPLEX for zlatm5,
Array, size (*ldb*, *n*). On exit *b* contains the *n*-by-*n* array *B* initialized according to *prtype*.

c REAL for slatm5,
DOUBLE PRECISION for dlatm5,
COMPLEX for clatm5,
DOUBLE COMPLEX for zlatm5,
Array, size (*ldc*, *n*). On exit *c* contains the *m*-by-*n* array *C* initialized according to *prtype*.

d REAL for slatm5,
DOUBLE PRECISION for dlatm5,
COMPLEX for clatm5,
DOUBLE COMPLEX for zlatm5,
Array, size (*ldd*, *m*). On exit *d* contains the *m*-by-*m* array *D* initialized according to *prtype*.

e REAL for slatm5,
DOUBLE PRECISION for dlatm5,
COMPLEX for clatm5,
DOUBLE COMPLEX for zlatm5,
Array, size (*lde*, *n*). On exit *e* contains the *n*-by-*n* array *E* initialized according to *prtype*.

<i>f</i>	<p>REAL for slatm5, DOUBLE PRECISION for dlatm5, COMPLEX for clatm5, DOUBLE COMPLEX for zlatm5, Array, size (<i>ldf</i>, <i>n</i>). On exit <i>f</i> contains the <i>m</i>-by-<i>n</i> array <i>F</i> initialized according to <i>prtype</i>.</p>
<i>r</i>	<p>REAL for slatm5, DOUBLE PRECISION for dlatm5, COMPLEX for clatm5, DOUBLE COMPLEX for zlatm5, Array, size (<i>ldr</i>, <i>n</i>). On exit <i>R</i> contains the <i>m</i>-by-<i>n</i> array <i>R</i> initialized according to <i>prtype</i>.</p>
<i>l</i>	<p>REAL for slatm5, DOUBLE PRECISION for dlatm5, COMPLEX for clatm5, DOUBLE COMPLEX for zlatm5, Array, size (<i>ldl</i>, <i>n</i>). On exit <i>l</i> contains the <i>m</i>-by-<i>n</i> array <i>L</i> initialized according to <i>prtype</i>.</p>

?latm6

Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

Syntax

```
call slatm6( type, n, a, lda, b, x, ldx, y, ldy, alpha, beta, wx, wy, s, dif )
call dlatm6( type, n, a, lda, b, x, ldx, y, ldy, alpha, beta, wx, wy, s, dif )
call clatm6( type, n, a, lda, b, x, ldx, y, ldy, alpha, beta, wx, wy, s, dif )
call zlatm6( type, n, a, lda, b, x, ldx, y, ldy, alpha, beta, wx, wy, s, dif )
```

Include Files

- mkl.fi

Description

The ?latm6 routine generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

There two kinds of test matrix pairs:

$$(A, B) = \text{inverse}(YH) * (Da, Db) * \text{inverse}(X)$$

Type 1:

$$D\alpha = \begin{bmatrix} 1+\alpha & 0 & 0 & 0 & 0 \\ 0 & 2+\alpha & 0 & 0 & 0 \\ 0 & 0 & 3+\alpha & 0 & 0 \\ 0 & 0 & 0 & 4+\alpha & 0 \\ 0 & 0 & 0 & 0 & 5+2 \end{bmatrix} \quad D\beta = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Type 2:

$$D\alpha = \begin{bmatrix} 1+i & 0 & 0 & 0 & 0 \\ 0 & 1-i & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & (1+\alpha)+(1+\beta)i & 0 \\ 0 & 0 & 0 & 0 & (1+\alpha)-(1+\beta)i \end{bmatrix} \quad D\beta = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

In both cases the same `inverse(YH)` and `inverse(X)` are used to compute (A, B) , giving the exact eigenvectors to (A, B) as (YH, X) :

$$YH = \begin{bmatrix} 1 & 0 & -y & y & -y \\ 0 & 1 & -y & y & -y \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad X = \begin{bmatrix} 1 & 0 & -x & -x & x \\ 0 & 1 & x & -x & -x \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

where a, b, x and y will have all values independently of each other.

Input Parameters

<i>type</i>	INTEGER. Specifies the problem type.
<i>n</i>	INTEGER. Size of the matrices <i>A</i> and <i>B</i> .
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> and of <i>b</i> .
<i>ldx</i>	INTEGER. The leading dimension of <i>x</i> .
<i>ldy</i>	INTEGER. The leading dimension of <i>y</i> .
<i>alpha, beta</i>	REAL for <code>slatm6</code> , DOUBLE PRECISION for <code>dlatm6</code> , COMPLEX for <code>clatm6</code> , DOUBLE COMPLEX for <code>zlatm6</code> , Weighting constants for matrix <i>A</i> .
<i>wx</i>	REAL for <code>slatm6</code> , DOUBLE PRECISION for <code>dlatm6</code> , COMPLEX for <code>clatm6</code> ,

DOUBLE COMPLEX for `zlatm6`,
 Constant for right eigenvector matrix.

`wy` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 COMPLEX for `clatm6`,
 DOUBLE COMPLEX for `zlatm6`,
 Constant for left eigenvector matrix.

Output Parameters

`a` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 COMPLEX for `clatm6`,
 DOUBLE COMPLEX for `zlatm6`,
 Array, size (lda, n) . On exit, `a` contains the n -by- n matrix initialized according to `type`.

`b` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 COMPLEX for `clatm6`,
 DOUBLE COMPLEX for `zlatm6`,
 Array, size (lda, n) . On exit, `b` contains the n -by- n matrix initialized according to `type`.

`x` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 COMPLEX for `clatm6`,
 DOUBLE COMPLEX for `zlatm6`,
 Array, size (ldx, n) . On exit, `x` contains the n -by- n matrix of right eigenvectors.

`y` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 COMPLEX for `clatm6`,
 DOUBLE COMPLEX for `zlatm6`,
 Array, size (ldy, n) . On exit, `y` is the n -by- n matrix of left eigenvectors.

`s` REAL for `slatm6`,
 DOUBLE PRECISION for `dlatm6`,
 REAL for `clatm6`,
 DOUBLE PRECISION for `zlatm6`,

Array, size (n). $s(i)$ is the reciprocal condition number for eigenvalue i .

dif

REAL for slatm6,

DOUBLE PRECISION for dlatm6,

REAL for clatm6,

DOUBLE PRECISION for zlatm6,

Array, size(n). $dif(i)$ is the reciprocal condition number for eigenvector i .

?latme

Generates random non-symmetric square matrices with specified eigenvalues.

Syntax

```
call slatme( n, dist, iseed, d, mode, cond, dmax, ei, rsign, upper, sim, ds, modes,
conds, kl, ku, anorm, a, lda, work, info )
```

```
call dlatme( n, dist, iseed, d, mode, cond, dmax, ei, rsign, upper, sim, ds, modes,
conds, kl, ku, anorm, a, lda, work, info )
```

```
call clatme( n, dist, iseed, d, mode, cond, dmax, ei, rsign, upper, sim, ds, modes,
conds, kl, ku, anorm, a, lda, work, info )
```

```
call zlatme( n, dist, iseed, d, mode, cond, dmax, ei, rsign, upper, sim, ds, modes,
conds, kl, ku, anorm, a, lda, work, info )
```

Include Files

- mkl.fi

Description

The ?latme routine generates random non-symmetric square matrices with specified eigenvalues. ?latme operates by applying the following sequence of operations:

1. Set the diagonal to d , where d may be input or computed according to *mode*, *cond*, *dmax*, and *rsign* as described below.
2. If *upper* = 'T', the upper triangle of a is set to random values out of distribution *dist*.
3. If *sim*='T', a is multiplied on the left by a random matrix X , whose singular values are specified by *ds*, *modes*, and *conds*, and on the right by X inverse.
4. If $kl < n-1$, the lower bandwidth is reduced to kl using Householder transformations. If $ku < n-1$, the upper bandwidth is reduced to ku .
5. If *anorm* is not negative, the matrix is scaled to have maximum-element-norm *anorm*.

NOTE

Since the matrix cannot be reduced beyond Hessenberg form, no packing options are available.

Input Parameters

n

INTEGER. The number of columns (or rows) of A .

<i>dist</i>	<p>CHARACTER*1. On entry, <i>dist</i> specifies the type of distribution to be used to generate the random eigen-/singular values, and on the upper triangle (see <i>upper</i>).</p> <p>If <i>dist</i> = 'U': uniform(0, 1)</p> <p>If <i>dist</i> = 'S': uniform(-1, 1)</p> <p>If <i>dist</i> = 'N': normal(0, 1)</p> <p>If <i>dist</i> = 'D': uniform on the complex disc $z < 1$.</p>
<i>iseed</i>	<p>INTEGER. Array, size 4.</p> <p>On entry <i>iseed</i> specifies the seed of the random number generator. The elements should lie between 0 and 4095 inclusive, and <i>iseed</i>(4) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.</p>
<i>d</i>	<p>REAL for slatme, DOUBLE PRECISION for dlatme, COMPLEX for clatme, DOUBLE COMPLEX for zlatme,</p> <p>Array, size (<i>n</i>). This array is used to specify the eigenvalues of <i>A</i>.</p> <p>If <i>mode</i> = 0, then <i>d</i> is assumed to contain the eigenvalues. Otherwise they are computed according to <i>mode</i>, <i>cond</i>, <i>dmax</i>, and <i>rsign</i> and placed in <i>d</i>.</p>
<i>mode</i>	<p>INTEGER. On entry <i>mode</i> describes how the eigenvalues are to be specified:</p> <p><i>mode</i> = 0 means use <i>d</i> (with <i>ei</i> for slatme and dlatme) as input.</p> <p><i>mode</i> = 1 sets $d(1) = 1$ and $d[1:n - 1] = 1.0/cond$.</p> <p><i>mode</i> = 2 sets $d(1:n-1) = 1$ and $d(n) = 1.0/cond$.</p> <p><i>mode</i> = 3 sets $d(i) = cond^{**}(-(i-1)/(n-1))$.</p> <p><i>mode</i> = 4 sets $d(i) = 1 - (i-1)/(n-1)*(1 - 1/cond)$.</p> <p><i>mode</i> = 5 sets <i>d</i> to random numbers in the range ($1/cond$, 1) such that their logarithms are uniformly distributed.</p> <p><i>mode</i> = 6 sets <i>d</i> to random numbers from same distribution as the rest of the matrix.</p> <p><i>mode</i> < 0 has the same meaning as <i>abs(mode)</i>, except that the order of the elements of <i>d</i> is reversed.</p> <p>Thus if <i>mode</i> is between 1 and 4, <i>d</i> has entries ranging from 1 to $1/cond$, if between -1 and -4, <i>d</i> has entries ranging from $1/cond$ to 1.</p>
<i>cond</i>	<p>REAL for slatme, DOUBLE PRECISION for dlatme, REAL for clatme, DOUBLE PRECISION for zlatme,</p>

On entry, this is used as described under *mode* above. If used, it must be ≥ 1 .

dmax

REAL for slatme,
DOUBLE PRECISION for dlatme,
COMPLEX for clatme,
DOUBLE COMPLEX for zlatme,

If *mode* is not -6, 0 or 6, the contents of *d* as computed according to *mode* and *cond* are scaled by $dmax / \max(\text{abs}(d(i)))$. Note that *dmax* needs not be positive or real: if *dmax* is negative or complex (or zero), *d* will be scaled by a negative or complex number (or zero). If *rsign*='F' then the largest (absolute) eigenvalue will be equal to *dmax*.

ei

CHARACTER*1. Used by slatme and dlatme only.

Array, size (*n*).

If *mode* = 0, and *ei*(1) is not ' ' (space character), this array specifies which elements of *d* (on input) are real eigenvalues and which are the real and imaginary parts of a complex conjugate pair of eigenvalues. The elements of *ei* may then only have the values 'R' and 'I'.

If *ei*(*j*) = 'R' and *ei*(*j* + 1) = 'I', then the *j*-th eigenvalue is $\text{cmplx}(d(j), d(j+1))$, and the (*j* + 1)-th is the complex conjugate thereof.

If *ei*(*j*) = *ei*(*j* + 1)='R', then the *j*-th eigenvalue is *d*(*j*) (i.e., real). *ei*(1) may not be 'I', nor may two adjacent elements of *ei* both have the value 'I'.

If *mode* is not 0, then *ei* is ignored. If *mode* is 0 and *ei*(1) = ' ', then the eigenvalues will all be real.

rsign

CHARACTER*1. If *mode* is not 0, 6, or -6, and *rsign* = 'T', then the elements of *d*, as computed according to *mode* and *cond*, are multiplied by a random sign (+1 or -1) for slatme and dlatme or by a complex number from the unit circle $|z| = 1$ for clatme and zlatme.

If *rsign* = 'F', the elements of *d* are not multiplied. *rsign* may only have the values 'T' or 'F'.

upper

CHARACTER*1. If *upper* = 'T', then the elements of *a* above the diagonal will be set to random numbers out of *dist*.

If *upper* = 'F', they will not. *upper* may only have the values 'T' or 'F'.

sim

CHARACTER*1. If *sim* = 'T', then *a* will be operated on by a "similarity transform", i.e., multiplied on the left by a matrix *X* and on the right by *X* inverse. $X = USV$, where *U* and *V* are random unitary matrices and *S* is a (diagonal) matrix of singular values specified by *ds*, *modes*, and *conds*.

If *sim* = 'F', then *a* will not be transformed.

ds

REAL for slatme,
DOUBLE PRECISION for dlatme,

REAL for `clatme`,

DOUBLE PRECISION for `zlatme`,

This array is used to specify the singular values of X , in the same way that d specifies the eigenvalues of a . If $mode = 0$, the ds contains the singular values, which may not be zero.

modes INTEGER.

Similar to *mode*, but for specifying the diagonal of S . *modes* = -6 and +6 are not allowed (since they would result in randomly ill-conditioned eigenvalues.)

conds REAL for `slatme`,

DOUBLE PRECISION for `dlatme`,

REAL for `clatme`,

DOUBLE PRECISION for `zlatme`,

Similar to *cond*, but for specifying the diagonal of S .

kl INTEGER. This specifies the lower bandwidth of the matrix. $kl = 1$ specifies upper Hessenberg form. If kl is at least $n-1$, then A will have full lower bandwidth.

ku INTEGER. This specifies the upper bandwidth of the matrix. $ku = 1$ specifies lower Hessenberg form.

If ku is at least $n-1$, then a will have full upper bandwidth.

If ku and kl are both at least $n-1$, then a will be dense. Only one of ku and kl may be less than $n-1$.

anorm REAL for `slatme`,

DOUBLE PRECISION for `dlatme`,

REAL for `clatme`,

DOUBLE PRECISION for `zlatme`,

If *anorm* is not negative, then a is scaled by a non-negative real number to make the maximum-element-norm of a to be *anorm*.

lda INTEGER. Number of rows of matrix A .

work REAL for `slatme`,

DOUBLE PRECISION for `dlatme`,

COMPLEX for `clatme`,

DOUBLE COMPLEX for `zlatme`,

Array, size $(3*n)$. Workspace.

Output Parameters

iseed INTEGER.

On exit, the seed is updated.

<i>d</i>	Modified if <i>mode</i> is nonzero.
<i>ds</i>	Modified if <i>mode</i> is nonzero.
<i>a</i>	REAL for slatme, DOUBLE PRECISION for dlatme, COMPLEX for clatme, DOUBLE COMPLEX for zlatme, Array, size (<i>lda</i> , <i>n</i>). On exit, <i>a</i> is the desired test matrix.
<i>info</i>	INTEGER. If <i>info</i> = 0, execution is successful. If <i>info</i> = -1, <i>n</i> is negative . If <i>info</i> = -2, <i>dist</i> is an illegal string. If <i>info</i> = -5, <i>mode</i> is not in range -6 to 6. If <i>info</i> = -6, <i>cond</i> is less than 1.0, and <i>mode</i> is not -6, 0, or 6 . If <i>info</i> = -9, <i>rsign</i> is not 'T' or 'F' . If <i>info</i> = -10, <i>upper</i> is not 'T' or 'F'. If <i>info</i> = -11, <i>sim</i> is not 'T' or 'F'. If <i>info</i> = -12, <i>modes</i> = 0 and <i>ds</i> has a zero singular value. If <i>info</i> = -13, <i>modes</i> is not in the range -5 to 5. If <i>info</i> = -14, <i>modes</i> is nonzero and <i>conds</i> is less than 1. . If <i>info</i> = -15, <i>kl</i> is less than 1. If <i>info</i> = -16, <i>ku</i> is less than 1, or <i>kl</i> and <i>ku</i> are both less than <i>n</i> -1. If <i>info</i> = -19, <i>lda</i> is less than <i>m</i> . If <i>info</i> = 1, error return from ?latm1 (computing <i>d</i>) . If <i>info</i> = 2, cannot scale to <i>dmax</i> (max. eigenvalue is 0) . If <i>info</i> = 3, error return from slatm1(for slatme and clatme), dlatm1 (for dlatme and zlatme) . If <i>info</i> = 4, error return from ?large. If <i>info</i> = 5, zero singular value from slatm1(for slatme and clatme), dlatm1(for dlatme and zlatme).

?latmr

Generates random matrices of various types.

Syntax

```
call slatmr (m, n, dist, iseed, sym, d, mode, cond, dmax, rsign, grade, dl, model,
condl, dr, moder, condr, pivtng, ipivot, kl, ku, sparse, anorm, pack, a, lda, iwork,
info)
```

```
call dlatmr (m, n, dist, iseed, sym, d, mode, cond, dmax, rsign, grade, dl, model,
condl, dr, moder, condr, pivtng, ipivot, kl, ku, sparse, anorm, pack, a, lda, iwork,
info)
```

```
call clatmr (m, n, dist, iseed, sym, d, mode, cond, dmax, rsign, grade, dl, model,
condl, dr, moder, condr, pivtng, ipivot, kl, ku, sparse, anorm, pack, a, lda, iwork,
info)
```

```
call zlatmr (m, n, dist, iseed, sym, d, mode, cond, dmax, rsign, grade, dl, model,
condl, dr, moder, condr, pivtng, ipivot, kl, ku, sparse, anorm, pack, a, lda, iwork,
info)
```

Description

The `?latmr` routine operates by applying the following sequence of operations:

1. Generate a matrix A with random entries of distribution *dist*:
 If *sym* = 'S', the matrix is symmetric,
 If *sym* = 'H', the matrix is Hermitian,
 If *sym* = 'N', the matrix is nonsymmetric.
2. Set the diagonal to D , where D may be input or computed according to *mode*, *cond*, *dmax* and *rsign* as described below.
3. Grade the matrix, if desired, from the left or right as specified by *grade*. The inputs *dl*, *model*, *condl*, *dr*, *moder* and *condr* also determine the grading as described below.
4. Permute, if desired, the rows and/or columns as specified by *pivtng* and *ipivot*.
5. Set random entries to zero, if desired, to get a random sparse matrix as specified by *sparse*.
6. Make A a band matrix, if desired, by zeroing out the matrix outside a band of lower bandwidth *kl* and upper bandwidth *ku*.
7. Scale A , if desired, to have maximum entry *anorm*.
8. Pack the matrix if desired. See options specified by the *pack* parameter.

NOTE

If two calls to `?latmr` differ only in the *pack* parameter, they generate mathematically equivalent matrices. If two calls to `?latmr` both have full bandwidth ($kl = m-1$ and $ku = n-1$), and differ only in the *pivtng* and *pack* parameters, then the matrices generated differ only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be and is not maintained with less than full bandwidth.

Input Parameters

<i>m</i>	INTEGER. Number of rows of A .
<i>n</i>	INTEGER. Number of columns of A .
<i>dist</i>	CHARACTER. On entry, <i>dist</i> specifies the type of distribution to be used to generate a random matrix . If <i>dist</i> = 'U', real and imaginary parts are independent uniform(0, 1). If <i>dist</i> = 'S', real and imaginary parts are independent uniform(-1, 1). If <i>dist</i> = 'N', real and imaginary parts are independent normal(0, 1). If <i>dist</i> = 'D', distribution is uniform on interior of unit disk.

<i>iseed</i>	<p>INTEGER. Array, size 4.</p> <p>On entry, <i>iseed</i> specifies the seed of the random number generator. They should lie between 0 and 4095 inclusive, and <i>iseed</i>(4) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.</p>
<i>sym</i>	<p>CHARACTER. If <i>sym</i> = 'S', generated matrix is symmetric.</p> <p>If <i>sym</i> = 'H', generated matrix is Hermitian.</p> <p>If <i>sym</i> = 'N', generated matrix is nonsymmetric.</p>
<i>d</i>	<p>REAL for slatmr, DOUBLE PRECISION for dlatmr, COMPLEX for clatmr, DOUBLE COMPLEX for zlatmr,</p> <p>On entry this array specifies the diagonal entries of the diagonal of <i>A</i>. <i>d</i> may either be specified on entry, or set according to <i>mode</i> and <i>cond</i> as described below. If the matrix is Hermitian, the real part of <i>d</i> is taken. May be changed on exit if <i>mode</i> is nonzero.</p>
<i>mode</i>	<p>INTEGER. On entry describes how <i>d</i> is to be used:</p> <p><i>mode</i> = 0 means use <i>d</i> as input.</p> <p><i>mode</i> = 1 sets $d(1)=1$ and $d(2:n)=1.0/cond$.</p> <p><i>mode</i> = 2 sets $d(1:n-1)=1$ and $d(n)=1.0/cond$.</p> <p><i>mode</i> = 3 sets $d(i)=cond^{*(-(i-1)/(n-1))}$.</p> <p><i>mode</i> = 4 sets $d(i)=1 - (i-1)/(n-1)*(1 - 1/cond)$.</p> <p><i>mode</i> = 5 sets <i>d</i> to random numbers in the range ($1/cond$, 1) such that their logarithms are uniformly distributed.</p> <p><i>mode</i> = 6 sets <i>d</i> to random numbers from same distribution as the rest of the matrix.</p> <p><i>mode</i> < 0 has the same meaning as <i>abs(mode)</i>, except that the order of the elements of <i>d</i> is reversed.</p> <p>Thus if <i>mode</i> is between 1 and 4, <i>d</i> has entries ranging from 1 to $1/cond$, if between -1 and -4, <i>D</i> has entries ranging from $1/cond$ to 1.</p>
<i>cond</i>	<p>REAL for slatmr, DOUBLE PRECISION for dlatmr, REAL for clatmr, DOUBLE PRECISION for zlatmr,</p> <p>On entry, used as described under <i>mode</i> above. If used, <i>cond</i> must be ≥ 1.</p>
<i>dmax</i>	<p>REAL for slatmr, DOUBLE PRECISION for dlatmr,</p>

COMPLEX for `clatmr`,

DOUBLE COMPLEX for `zlatmr`,

If *mode* is not -6, 0, or 6, the diagonal is scaled by $dmax / \max(\text{abs}(d(i)))$, so that maximum absolute entry of diagonal is $\text{abs}(dmax)$. If *dmax* is complex (or zero), the diagonal is scaled by a complex number (or zero).

rsign

CHARACTER. If *mode* is not -6, 0, or 6, specifies the sign of the diagonal as follows:

For `slatmr` and `dlatmr`, if *rsign* = 'T', diagonal entries are multiplied 1 or -1 with a probability of 0.5.

For `clatmr` and `zlatmr`, if *rsign* = 'T', diagonal entries are multiplied by a random complex number uniformly distributed with absolute value 1.

If *rsign* = 'F', diagonal entries are unchanged.

grade

CHARACTER. Specifies grading of matrix as follows:

If *grade* = 'N', there is no grading

If *grade* = 'L', matrix is premultiplied by `diag(dl)` (only if matrix is nonsymmetric)

If *grade* = 'R', matrix is postmultiplied by `diag(dr)` (only if matrix is nonsymmetric)

If *grade* = 'B', matrix is premultiplied by `diag(dl)` and postmultiplied by `diag(dr)` (only if matrix is nonsymmetric)

If *grade* = 'H', matrix is premultiplied by `diag(dl)` and postmultiplied by `diag(conjg(dl))` (only if matrix is Hermitian or nonsymmetric)

If *grade* = 'S', matrix is premultiplied by `diag(dl)` and postmultiplied by `diag(dl)` (only if matrix is symmetric or nonsymmetric)

If *grade* = 'E', matrix is premultiplied by `diag(dl)` and postmultiplied by `inv(diag(dl))` (only if matrix is nonsymmetric)

NOTE

if *grade* = 'E', then *m* must equal *n*.

dl

REAL for `slatmr`,

DOUBLE PRECISION for `dlatmr`,

COMPLEX for `clatmr`,

DOUBLE COMPLEX for `zlatmr`,

Array, size (*m*).

If *model* = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under *grade* above.

If *model* is not zero, then *dl* is set according to *model* and *condl*, analogous to the way *D* is set according to *mode* and *cond* (except there is no *dmax* parameter for *dl*).

If *grade* = 'E', then *dl* cannot have zero entries.

	Not referenced if <i>grade</i> = 'N' or 'R'. Changed on exit.
<i>model</i>	INTEGER. This specifies how the diagonal array <i>dl</i> is computed, just as <i>mode</i> specifies how <i>D</i> is computed.
<i>condl</i>	<p>REAL for <i>slatmr</i>,</p> <p>DOUBLE PRECISION for <i>dlatmr</i>,</p> <p>REAL for <i>clatmr</i>,</p> <p>DOUBLE PRECISION for <i>zlatmr</i>,</p> <p>When <i>model</i> is not zero, this specifies the condition number of the computed <i>dl</i>.</p>
<i>dr</i>	<p>REAL for <i>slatmr</i>,</p> <p>DOUBLE PRECISION for <i>dlatmr</i>,</p> <p>COMPLEX for <i>clatmr</i>,</p> <p>DOUBLE COMPLEX for <i>zlatmr</i>,</p> <p>If <i>morder</i> = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under <i>grade</i> above.</p> <p>If <i>morder</i> is not zero, then <i>dr</i> is set according to <i>morder</i> and <i>condr</i>, analogous to the way <i>d</i> is set according to <i>mode</i> and <i>cond</i> (except there is no <i>dmax</i> parameter for <i>dr</i>).</p> <p>Not referenced if <i>grade</i> = 'N', 'L', 'H', 'S' or 'E'.</p>
<i>morder</i>	INTEGER. This specifies how the diagonal array <i>dr</i> is to be computed, just as <i>mode</i> specifies how <i>d</i> is to be computed.
<i>condr</i>	<p>REAL for <i>slatmr</i> and <i>clatmr</i>,</p> <p>DOUBLE PRECISION for <i>dlatmr</i> and <i>zlatmr</i>,</p> <p>When <i>morder</i> is not zero, this specifies the condition number of the computed <i>dr</i>.</p>
<i>pivtnng</i>	<p>CHARACTER. On entry specifies pivoting permutations as follows:</p> <p>If <i>pivtnng</i> = 'N' or ' ': no pivoting permutation.</p> <p>If <i>pivtnng</i> = 'L': left or row pivoting (matrix must be nonsymmetric).</p> <p>If <i>pivtnng</i> = 'R': right or column pivoting (matrix must be nonsymmetric).</p> <p>If <i>pivtnng</i> = 'B' or 'F': both or full pivoting, i.e., on both sides. In this case, <i>m</i> must equal <i>n</i>.</p> <p>If two calls to ?<i>latmr</i> both have full bandwidth (<i>kl</i> = <i>m</i> - 1 and <i>ku</i> = <i>n</i>-1), and differ only in the <i>pivtnng</i> and <i>pack</i> parameters, then the matrices generated differs only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be maintained with less than full bandwidth.</p>
<i>ipivot</i>	INTEGER. Array, size (<i>n</i> or <i>m</i>) This array specifies the permutation used. After the basic matrix is generated, the rows, columns, or both are permuted.

If row pivoting is selected, `zlatmr` starts with the last row and interchanges row m and row $ipivot(m)$, then moves to the next-to-last row, interchanging rows $(m-1)$ and row $ipivot(m-1)$, and so on. In terms of "2-cycles", the permutation is $(1\ ipivot(1))\ (2\ ipivot(2))\ \dots\ (m\ ipivot(m))$ where the rightmost cycle is applied first. This is the inverse of the effect of pivoting in LINPACK. The idea is that factoring (with pivoting) an identity matrix which has been inverse-pivoted in this way should result in a pivot vector identical to $ipivot$. Not referenced if $pivtnp = 'N'$.

sparse

```
REAL for slatmr,
DOUBLE PRECISION for dlatmr,
REAL for clatmr,
DOUBLE PRECISION for zlatmr,
```

On entry, specifies the sparsity of the matrix if a sparse matrix is to be generated. *sparse* should lie between 0 and 1. To generate a sparse matrix, for each matrix entry a uniform (0, 1) random number x is generated and compared to *sparse*; if x is larger the matrix entry is unchanged and if x is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries is set to zero.

kl

INTEGER. On entry, specifies the lower bandwidth of the matrix. For example, $kl = 0$ implies upper triangular, $kl = 1$ implies upper Hessenberg, and kl at least $m-1$ implies the matrix is not banded. Must equal ku if matrix is symmetric or Hermitian.

ku

INTEGER. On entry, specifies the upper bandwidth of the matrix. For example, $ku = 0$ implies lower triangular, $ku = 1$ implies lower Hessenberg, and ku at least $n-1$ implies the matrix is not banded. Must equal kl if matrix is symmetric or Hermitian.

anorm

```
REAL for slatmr,
DOUBLE PRECISION for dlatmr,
REAL for clatmr,
DOUBLE PRECISION for zlatmr,
```

On entry, specifies maximum entry of output matrix (output matrix is multiplied by a constant so that its largest absolute entry equal *anorm*) if *anorm* is nonnegative. If *anorm* is negative no scaling is done.

pack

```
for slatmr,
for dlatmr,
for clatmr,
for zlatmr,
```

On entry, specifies packing of matrix as follows:

If *pack* = 'N': no packing

If *pack* = 'U': zero out all subdiagonal entries (if symmetric or Hermitian)

If *pack* = 'L': zero out all superdiagonal entries (if symmetric or Hermitian)

If *pack* = 'C': store the upper triangle columnwise (only if matrix symmetric or Hermitian or square upper triangular)

If *pack* = 'R': store the lower triangle columnwise (only if matrix symmetric or Hermitian or square lower triangular) (same as upper half rowwise if symmetric) (same as conjugate upper half rowwise if Hermitian)

If *pack* = 'B': store the lower triangle in band storage scheme (only if matrix symmetric or Hermitian)

If *pack* = 'Q': store the upper triangle in band storage scheme (only if matrix symmetric or Hermitian)

If *pack* = 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store *A* in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

LAPACK storage scheme	Value of <i>pack</i>
GB	'Z'
PB, HB or TB	'B' or 'Q'
PP, HP or TP	'C' or 'R'

If two calls to `?latmr` differ only in the *pack* parameter, they generate mathematically equivalent matrices.

lda

INTEGER. On entry, *lda* specifies the first dimension of *a* as declared in the calling program.

If *pack* = 'N', 'U' or 'L', *lda* must be at least $\max(1, m)$.

If *pack* = 'C' or 'R', *lda* must be at least 1.

If *pack* = 'B', or 'Q', *lda* must be $\min(ku + 1, n)$.

If *pack* = 'Z', *lda* must be at least $k_{uu} + k_{ll} + 1$, where $k_{uu} = \min(ku, n-1)$ and $k_{ll} = \min(kl, n-1)$.

iwork

INTEGER. Array, size (*n* or *m*). Workspace. Not referenced if *pivtn* = 'N'. Changed on exit.

Output Parameters

iseed

On exit, the seed is changed.

d

May be changed on exit if *mode* is nonzero.

dl

On exit, array is changed.

dr

On exit, array is changed.

a

REAL for `slatmr`,
DOUBLE PRECISION for `dlatmr`,

COMPLEX for `clatmr`,

DOUBLE COMPLEX for `zlatmr`,

On exit, *a* is the desired test matrix. Only those entries of *a* which are significant on output is referenced (even if *a* is in packed or band storage format). The unoccupied corners of *a* in band format are zeroed out.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -1, *m* is negative or unequal to *n* and *sym* = 'S' or 'H'.

If *info* = -2, *n* is negative .

If *info* = -3, *dist* is an illegal string.

If *info* = -5, *sym* is an illegal string..

If *info* = -7, *mode* is not in range -6 to 6.

If *info* = -8, *cond* is less than 1.0, and *mode* is neither -6, 0 nor 6.

If *info* = -10, *mode* is neither -6, 0 nor 6 and *rsign* is an illegal string.

If *info* = -11, *grade* is an illegal string, or *grade* = 'E' and *m* is not equal to *n*, or *grade*='L', 'R', 'B', 'S' or 'E' and *sym* = 'H', or *grade* = 'L', 'R', 'B', 'H' or 'E' and *sym* = 'S'

If *info* = -12, *grade* = 'E' and *dl* contains zero .

If *info* = -13, *model* is not in range -6 to 6 and *grade* = 'L', 'B', 'H', 'S' or 'E' .

If *info* = -14, *concl* is less than 1.0, *grade* = 'L', 'B', 'H', 'S' or 'E', and *model* is neither -6, 0 nor 6.

If *info* = -16, *moder* is not in range -6 to 6 and *grade* = 'R' or 'B' .

If *info* = -17, *condr* is less than 1.0, *grade* = 'R' or 'B', and *moder* is neither -6, 0 nor 6 .

If *info* = -18, *pivtnng* is an illegal string, or *pivtnng* = 'B' or 'F' and *m* is not equal to *n*, or *pivtnng* = 'L' or 'R' and *sym* = 'S' or 'H'.

If *info* = -19, *ipivot* contains out of range number and *pivtnng* is not equal to 'N' .

If *info* = -20, *kl* is negative.

If *info* = -21, *ku* is negative, or *sym* = 'S' or 'H' and *ku* not equal to *kl* .

If *info* = -22, *sparse* is not in range 0 to 1.

If *info* = -24, *pack* is an illegal string, or *pack* = 'U', 'L', 'B' or 'Q' and *sym* = 'N', or *pack* = 'C' and *sym* = 'N' and either *kl* is not equal to 0 or *n* is not equal to *m*, or *pack* = 'R' and *sym* = 'N', and either *ku* is not equal to 0 or *n* is not equal to *m* .

If *info* = -26, *lda* is too small .

If *info* = 1, error return from ?latm1 (computing *D*) .

If *info* = 2, cannot scale to *dmax* (max. entry is 0) .

If *info* = 3, error return from ?latm1(computing *dl*) .

If *info* = 4, error return from ?latm1(computing *dr*) .

If *info* = 5, *anorm* is positive, but matrix constructed prior to attempting to scale it to have norm *anorm*, is zero .

?latdf

Uses the LU factorization of the *n*-by-*n* matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.

Syntax

```
call slatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call dlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call clatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call zlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
```

Include Files

- mkl.fi

Description

The routine ?latdf uses the LU factorization of the *n*-by-*n* matrix *Z* computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate by solving $Z^*x = b$ for *x*, and choosing the right-hand side *b* such that the norm of *x* is as large as possible. On entry *rhs* = *b* holds the contribution from earlier solved sub-systems, and on return *rhs* = *x*.

The factorization of *Z* returned by ?getc2 has the form $Z = P^*L^*U^*Q$, where *P* and *Q* are permutation matrices. *L* is lower triangular with unit diagonal elements and *U* is upper triangular.

Input Parameters

<i>ijob</i>	INTEGER. <i>ijob</i> = 2: First compute an approximative null-vector <i>e</i> of <i>Z</i> using ?gecon, <i>e</i> is normalized, and solve for $Z^*x = \pm e$ with the sign giving the greater value of 2-norm(<i>x</i>). This option is about 5 times as expensive as default. <i>ijob</i> ≠ 2 (default): Local look ahead strategy where all entries of the right-hand side <i>b</i> is chosen as either +1 or -1 .
<i>n</i>	INTEGER. The number of columns of the matrix <i>Z</i> .
<i>z</i>	REAL for slatdf/clatdf DOUBLE PRECISION for dlatdf/zlatdf. Array, DIMENSION (<i>ldz</i> , <i>n</i>) On entry, the LU part of the factorization of the <i>n</i> -by- <i>n</i> matrix <i>Z</i> computed by ?getc2: $Z = P^*L^*U^*Q$.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>Z</i> . $lda \geq \max(1, n)$.

<i>rhs</i>	<p>REAL for slatdf/clatdf</p> <p>DOUBLE PRECISION for dlatdf/zlatdf.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>On entry, <i>rhs</i> contains contributions from other subsystems.</p>
<i>rdsum</i>	<p>REAL for slatdf/clatdf</p> <p>DOUBLE PRECISION for dlatdf/zlatdf.</p> <p>On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ?tgsyL, where the scaling factor <i>rdscal</i> has been factored out. If <i>trans</i> = 'T', <i>rdsum</i> is not touched.</p> <p>Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsyL.</p>
<i>rdscal</i>	<p>REAL for slatdf/clatdf</p> <p>DOUBLE PRECISION for dlatdf/zlatdf.</p> <p>On entry, scaling factor used to prevent overflow in <i>rdsum</i>.</p> <p>If <i>trans</i> = 'T', <i>rdscal</i> is not touched.</p> <p>Note that <i>rdscal</i> only makes sense when ?tgsy2 is called by ?tgsyL.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The pivot indices; for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv</i>(<i>i</i>).</p>
<i>jpiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The pivot indices; for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv</i>(<i>j</i>).</p>

Output Parameters

<i>rhs</i>	On exit, <i>rhs</i> contains the solution of the subsystem with entries according to the value of <i>ijob</i> .
<i>rdsum</i>	<p>On exit, the corresponding sum of squares updated with the contributions from the current sub-system.</p> <p>If <i>trans</i> = 'T', <i>rdsum</i> is not touched.</p>
<i>rdscal</i>	<p>On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i>.</p> <p>If <i>trans</i> = 'T', <i>rdscal</i> is not touched.</p>

?latps

Solves a triangular system of equations with the matrix held in packed storage.

Syntax

```
call slatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call dlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call clatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call zlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
```

Include Files

- mkl.fi

Description

The routine ?latps solves one of the triangular systems

$A*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem does not cause overflow, the Level 2 BLAS routine ?tpsv is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': upper triangular = 'L': uower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular. = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.

<i>ap</i>	<p>REAL for slatps</p> <p>DOUBLE PRECISION for dlatps</p> <p>COMPLEX for clatps</p> <p>DOUBLE COMPLEX for zlatps.</p> <p>Array, DIMENSION $(n(n+1)/2)$.</p> <p>The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array <i>ap</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;</p> <p>if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.</p>
<i>x</i>	<p>REAL for slatpsDOUBLE PRECISION for dlatps</p> <p>COMPLEX for clatps</p> <p>DOUBLE COMPLEX for zlatps.</p> <p>Array, DIMENSION (n)</p> <p>On entry, the right hand side b of the triangular system.</p>
<i>cnorm</i>	<p>REAL for slatps/clatps</p> <p>DOUBLE PRECISION for dlatps/zlatps.</p> <p>Array, DIMENSION (n).</p> <p>If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i>(j) contains the norm of the off-diagonal part of the j-th column of A.</p> <p>If <i>trans</i> = 'N', <i>cnorm</i>(j) must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i>(j) must be greater than or equal to the 1-norm.</p>
Output Parameters	
<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .
<i>scale</i>	<p>REAL for slatps/clatps</p> <p>DOUBLE PRECISION for dlatps/zlatps.</p> <p>The scaling factor s for the triangular system as described above.</p> <p>If <i>scale</i> = 0, the matrix A is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to $A*x = 0$.</p>
<i>cnorm</i>	If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm</i> (j) returns the 1-norm of the off-diagonal part of the j -th column of A .
<i>info</i>	<p>INTEGER.</p> <p>= 0: successful exit</p> <p>< 0: if <i>info</i> = $-k$, the k-th argument had an illegal value</p>

?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call slatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call dlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call clatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call zlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
```

Include Files

- mkl.fi

Description

The routine ?latrd reduces nb rows and columns of a real symmetric or complex Hermitian matrix A to symmetric/Hermitian tridiagonal form by an orthogonal/unitary similarity transformation $Q^T A Q$ for real flavors, $Q^H A Q$ for complex flavors, and returns the matrices V and W which are needed to apply the transformation to the unreduced part of A .

If $uplo = 'U'$, ?latrd reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = 'L'$, ?latrd reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by ?sytrd/?hetrd.

Input Parameters

$uplo$	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored: = 'U': upper triangular = 'L': lower triangular
n	INTEGER. The order of the matrix A .
nb	INTEGER. The number of rows and columns to be reduced.
a	REAL for slatrd DOUBLE PRECISION for dlatrd COMPLEX for clatrd DOUBLE COMPLEX for zlatrd. Array, DIMENSION (lda, n). On entry, the symmetric/Hermitian matrix A

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a . $lda \geq (1, n)$.

ldw INTEGER.

The leading dimension of the output array w . $ldw \geq \max(1, n)$.

Output Parameters

a On exit, if $uplo = 'U'$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of a ; the elements above the diagonal with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if $uplo = 'L'$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of a ; the elements below the diagonal with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

e REAL for slatrd/clatrd

DOUBLE PRECISION for dlatrd/zlatrd.

If $uplo = 'U'$, $e(n-nb:n-1)$ contains the superdiagonal elements of the last nb columns of the reduced matrix;

if $uplo = 'L'$, $e(1:nb)$ contains the subdiagonal elements of the first nb columns of the reduced matrix.

τ REAL for slatrd

DOUBLE PRECISION for dlatrd

COMPLEX for clatrd

DOUBLE COMPLEX for zlatrd.

Array, DIMENSION (lda, n) .

The scalar factors of the elementary reflectors, stored in $\tau(n-nb:n-1)$ if $uplo = 'U'$, and in $\tau(1:nb)$ if $uplo = 'L'$.

w REAL for slatrd

DOUBLE PRECISION for dlatrd

COMPLEX for clatrd

DOUBLE COMPLEX for zlatrd.

Array, DIMENSION (ldw, n) .

The n -by- nb matrix W required to update the unreduced part of A .

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $a(1:i-1, i)$, and τ in $\tau(i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form $H(i) = I - \tau v v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+1:n)$ is stored on exit in $a(i+1:n, i)$, and τ in $\tau(i)$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2k update of the form:

$$A := A - VW' - WV'.$$

The contents of a on exit are illustrated by the following examples with $n = 5$ and $nb = 2$:

if $uplo = 'U'$:	if $uplo = 'L'$
$\begin{bmatrix} a & a & a & v_1 & v_1 \\ & a & a & v_1 & v_1 \\ & & a & 1 & v_1 \\ & & & d & 1 \\ & & & & d \end{bmatrix}$	$\begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_1 & a & a & \\ v_1 & v_1 & a & a & a \end{bmatrix}$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

slatrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call slatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call dlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call clatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call zlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
```

Include Files

- `mkl.fi`

Description

The routine solves one of the triangular systems

$$A^*x = s*b, \text{ or } A^T*x = s*b, \text{ or } A^H*x = s*b \text{ (for complex flavors)}$$

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine `?trsv` is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A^*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A^*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': non-unit triangular = 'N': non-unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$
<i>a</i>	REAL for <code>slatrs</code> DOUBLE PRECISION for <code>dlatrs</code> COMPLEX for <code>clatrs</code> DOUBLE COMPLEX for <code>zlatrs</code> . Array, DIMENSION (<i>lda</i> , n). Contains the triangular matrix A .

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *A* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *A* is not referenced.

If *diag* = 'U', the diagonal elements of *A* are also not referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

x REAL for slatrs
DOUBLE PRECISION for dlatrs
COMPLEX for clatrs
DOUBLE COMPLEX for zlatrs.

Array, DIMENSION (*n*).

On entry, the right hand side *b* of the triangular system.

cnorm REAL for slatrs/clatrs
DOUBLE PRECISION for dlatrs/zlatrs.

Array, DIMENSION (*n*).

If *normin* = 'Y', *cnorm* is an input argument and *cnorm* (*j*) contains the norm of the off-diagonal part of the *j*-th column of *A*.

If *trans* = 'N', *cnorm* (*j*) must be greater than or equal to the infinity-norm, and if *trans* = 'T' or 'C', *cnorm* (*j*) must be greater than or equal to the 1-norm.

Output Parameters

x On exit, *x* is overwritten by the solution vector *x*.

scale REAL for slatrs/clatrs
DOUBLE PRECISION for dlatrs/zlatrs.
Array, DIMENSION (*lda*, *n*). The scaling factor *s* for the triangular system as described above.
If *scale* = 0, the matrix *A* is singular or badly scaled, and the vector *x* is an exact or approximate solution to $A^*x = 0$.

cnorm If *normin* = 'N', *cnorm* is an output argument and *cnorm* (*j*) returns the 1-norm of the off-diagonal part of the *j*-th column of *A*.

info INTEGER.
= 0: successful exit
< 0: if *info* = -*k*, the *k*-th argument had an illegal value

Application Notes

A rough bound on x is computed; if that is less than overflow, `?trsv` is called, otherwise, specific code is used which checks for possible overflow or divide-by-zero at every operation.

A columnwise scheme is used for solving $Ax = b$. The basic algorithm if A is lower triangular is

```
x[1:n] := b[1:n]
for j = 1, ..., n
  x(j) := x(j) / A(j,j)
  x[j+1:n] := x[j+1:n] - x(j)*a[j+1:n,j]
end
```

Define bounds on the components of x after j iterations of the loop:

```
M(j) = bound on x[1:j]
G(j) = bound on x[j+1:n]
```

Initially, let $M(0) = 0$ and $G(0) = \max\{x(i), i=1, \dots, n\}$.

Then for iteration $j+1$ we have

```
M(j+1) ≤ G(j) / | a(j+1,j+1) |
G(j+1) ≤ G(j) + M(j+1)*| a[j+2:n,j+1] |
≤ G(j) (1 + cnorm(j+1)/ | a(j+1,j+1) |,
```

where $cnorm(j+1)$ is greater than or equal to the infinity-norm of column $j+1$ of a , not counting the diagonal. Hence

$$G(j) \leq G(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

and

$$|x(j)| \leq (G(0)/|A(j,j)|) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

Since $|x(j)| \leq M(j)$, we use the Level 2 BLAS routine `?trsv` if the reciprocal of the largest $M(j)$, $j=1, \dots, n$, is larger than $\max(\text{underflow}, 1/\text{overflow})$.

The bound on $x(j)$ is also used to determine when a step in the columnwise method can be performed without fear of overflow. If the computed bound is greater than a large constant, x is scaled to prevent overflow, but if the bound overflows, x is set to 0, $x(j)$ to 1, and scale to 0, and a non-trivial solution to $Ax = 0$ is found.

Similarly, a row-wise scheme is used to solve $A^T x = b$ or $A^H x = b$. The basic algorithm for A upper triangular is

```
for j = 1, ..., n
  x(j) := ( b(j) - A[1:j-1,j]' x[1:j-1] ) / A(j,j)
end
```

We simultaneously compute two bounds

$G(j) = \text{bound on } (b(i) - A[1:i-1, i]' * x[1:i-1]), 1 \leq i \leq j$

$M(j) = \text{bound on } x(i), 1 \leq i \leq j$

The initial values are $G(0) = 0, M(0) = \max\{b(i), i=1, \dots, n\}$, and we add the constraint $G(j) \geq G(j-1)$ and $M(j) \geq M(j-1)$ for $j \geq 1$.

Then the bound on $x(j)$ is

$M(j) \leq M(j-1) * (1 + \text{cnorm}(j)) / |A(j, j)|$

$$\leq M(0) \prod_{1 \leq i \leq j} (1 + \text{cnorm}(i) / |A(i, i)|)$$

and we can safely call ?trsv if $1/M(n)$ and $1/G(n)$ are both greater than $\max(\text{underflow}, 1/\text{overflow})$.

?latrz

Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.

Syntax

```
call slatz( m, n, l, a, lda, tau, work )
call dlatrz( m, n, l, a, lda, tau, work )
call clatz( m, n, l, a, lda, tau, work )
call zlatrz( m, n, l, a, lda, tau, work )
```

Include Files

- mkl.fi

Description

The routine ?latrz factors the m -by- $(m+l)$ real/complex upper trapezoidal matrix

$[A1 \ A2] = [A(1:m, 1:m) \ A(1:m, n-l+1:n)]$

as $(R \ 0) * Z$, by means of orthogonal/unitary transformations. Z is an $(m+l)$ -by- $(m+l)$ orthogonal/unitary matrix and R and $A1$ are m -by- m upper triangular matrices.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
l	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder vectors. $n-m \geq l \geq 0$.
a	REAL for slatz DOUBLE PRECISION for dlatrz COMPLEX for clatz

DOUBLE COMPLEX for zlatrz.

Array, DIMENSION (*lda*, *n*).

On entry, the leading *m*-by-*n* upper trapezoidal part of the array *a* must contain the matrix to be factorized.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, m)$.

work REAL for slatz

DOUBLE PRECISION for dlatrz

COMPLEX for clatz

DOUBLE COMPLEX for zlatrz.

Workspace array, DIMENSION (*m*).

Output Parameters

a On exit, the leading *m*-by-*m* upper triangular part of *a* contains the upper triangular matrix *R*, and elements *n*-*l*+1 to *n* of the first *m* rows of *a*, with the array *tau*, represent the orthogonal/unitary matrix *Z* as a product of *m* elementary reflectors.

tau REAL for slatz

DOUBLE PRECISION for dlatrz

COMPLEX for clatz

DOUBLE COMPLEX for zlatrz.

Array, DIMENSION (*m*).

The scalar factors of the elementary reflectors.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, *z*(*k*), which is used to introduce zeros into the (*m* - *k* + 1)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where for real flavors

$$T(k) = I - \tau u u^* T(k)^T, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

and for complex flavors

$$T(k) = I - \tau u u^H, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an l -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of $A2$.

The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $A2$, such that the elements of $z(k)$ are in $a(k, l+1), \dots, a(k, n)$.

The elements of r are returned in the upper triangular part of $A1$.

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

?lauu2

Computes the product $U * U^T (U * U^H)$ or $L^T * L (L^H * L)$, where U and L are upper or lower triangular matrices (unblocked algorithm).

Syntax

```
call slauu2( uplo, n, a, lda, info )
call dlauu2( uplo, n, a, lda, info )
call clauu2( uplo, n, a, lda, info )
call zlauu2( uplo, n, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine ?lauu2 computes the product $U * U^T$ or $L^T * L$ for real flavors, and $U * U^H$ or $L^H * L$ for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in A .

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in A .

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

$uplo$	CHARACTER*1. Specifies whether the triangular factor stored in the array a is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
n	INTEGER. The order of the triangular factor U or L . $n \geq 0$.

a REAL for slauu2
 DOUBLE PRECISION for dlauu2
 COMPLEX for clauu2
 DOUBLE COMPLEX for zlauu2.
 Array, DIMENSION (*lda*, *n*). On entry, the triangular factor *U* or *L*.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit,
 if *uplo* = 'U', then the upper triangle of *a* is overwritten with the upper triangle of the product U^*U^T (U^*U^H);
 if *uplo* = 'L', then the lower triangle of *a* is overwritten with the lower triangle of the product L^T*L (L^H*L).

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*k*, the *k*-th argument had an illegal value

?lauum

Computes the product $U^*U^T(U^*U^H)$ or $L^T*L(L^H*L)$, where *U* and *L* are upper or lower triangular matrices (blocked algorithm).

Syntax

```
call slauum( uplo, n, a, lda, info )
call dlauum( uplo, n, a, lda, info )
call clauum( uplo, n, a, lda, info )
call zlauum( uplo, n, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine ?lauum computes the product U^*U^T or L^T*L for real flavors, and U^*U^H or L^H*L for complex flavors. Here the triangular factor *U* or *L* is stored in the upper or lower triangular part of the array *a*.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor *U* in *A*.

If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor *L* in *A*.

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

The data types are given for the Fortran interface.

uplo CHARACTER*1.

Specifies whether the triangular factor stored in the array *a* is upper or lower triangular:

= 'U': Upper triangular

= 'L': Lower triangular

n INTEGER. The order of the triangular factor *U* or *L*. $n \geq 0$.

a REAL for slauum
DOUBLE PRECISION for dlauum
COMPLEX for clauum
DOUBLE COMPLEX for zlauum .

Array of size (lda, n) .

On entry, the triangular factor *U* or *L*.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit,
if *uplo* = 'U', then the upper triangle of *a* is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$;
if *uplo* = 'L', then the lower triangle of *a* is overwritten with the lower triangle of the product $L^T*L(L^H*L)$.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*k*, the *k*-th parameter had an illegal value.
If *info* = -1011, memory allocation error occurred.

?orbdb1/?unbdb1

Simultaneously bidiagonalizes the blocks of a tall and skinny matrix with orthonormal columns.

Syntax

```
call sorbdb1( m, p, q, x11, ldx11, x21, ldx21, theta, phi, taup1, taup2, tauq1, work,
lwork, info )
```

```
call dorbdb1( m, p, q, x11, ldx11, x21, ldx21, theta, phi, taup1, taup2, tauq1, work,
lwork, info )
```

```
call cunbdb1( m, p, q, x11, ldx11, x21, ldx21, theta, phi, taup1, taup2, tauq1, work,
lwork, info )
```

```
call zunbdb1( m, p, q, x11, ldx11, x21, ldx21, theta, phi, taup1, taup2, tauq1, work,
lwork, info )
```

Include Files

- `mk1.fi`, `lapack.f90`

Description

The routines `?orbdb1/?unbdb1` simultaneously bidiagonalize the blocks of a tall and skinny matrix X with orthonormal columns:

$$\begin{bmatrix} x_{11} \\ x_{21} \end{bmatrix} = \begin{bmatrix} p_1 & | \\ \hline & p_2 \end{bmatrix} \begin{bmatrix} b_{11} \\ 0 \\ b_{21} \\ 0 \end{bmatrix} q_1^T$$

The size of x_{11} is p by q , and x_{21} is $(m - p)$ by q . q must not be larger than p , $m - p$, or $m - q$.

Tall and Skinny Matrix Routines

$q \leq \min(p, m - p, m - q)$	<code>?orbdb1/?unbdb1</code>
$p \leq \min(q, m - p, m - q)$	<code>?orbdb2/?unbdb2</code>
$m - p \leq \min(p, q, m - q)$	<code>?orbdb3/?unbdb3</code>
$m - q \leq \min(p, q, m - p)$	<code>?orbdb4/?unbdb4</code>

The orthogonal/unitary matrices p_1 , p_2 , and q_1 are p -by- p , $(m - p)$ -by- $(m - p)$, $(m - q)$ -by- $(m - q)$, respectively.

p_1 , p_2 , and q_1 are represented as products of elementary reflectors. See the description of `?orcsd2by1/?uncsd2by1` for details on generating p_1 , p_2 , and q_1 using `?orgqr` and `?orglq`.

The upper-bidiagonal matrices b_{11} and b_{12} of size q by q are represented implicitly by angles $\theta(1), \dots, \theta(q)$ and $\phi(1), \dots, \phi(q - 1)$. Every entry in each bidiagonal band is a product of a sine or cosine of θ with a sine or cosine of ϕ . See [Sutton09] or the description of `?orcsd/?uncsd` for details.

Input Parameters

m	INTEGER. The number of rows in x_{11} plus the number of rows in x_{21} .
p	INTEGER. The number of rows in x_{11} . $0 \leq p \leq m$.
q	INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq \min(p, m - p, m - q)$.
x_{11}	REAL for <code>sorbdb1</code> DOUBLE PRECISION for <code>dorbdb1</code> COMPLEX for <code>cunbdb1</code> DOUBLE COMPLEX for <code>zunbdb1</code> Array, DIMENSION $(ldx11, q)$. On entry, the top block of the orthogonal/unitary matrix to be reduced.
$ldx11$	INTEGER. The leading dimension of the array X_{11} . $ldx11 \geq p$.
x_{21}	REAL for <code>sorbdb1</code> DOUBLE PRECISION for <code>dorbdb1</code> COMPLEX for <code>cunbdb1</code>

DOUBLE COMPLEX for zunbdb1

Array, DIMENSION ($ldx21, q$).

On entry, the bottom block of the orthogonal/unitary matrix to be reduced.

ldx21

INTEGER. The leading dimension of the array X_{21} . $ldx21 \geq m - p$.

work

REAL for sorbdb1

DOUBLE PRECISION for dorbdb1

COMPLEX for cunbdb1

DOUBLE COMPLEX for zunbdb1

Workspace array, DIMENSION (*lwork*).

lwork

INTEGER. The size of the *work* array. $lwork \geq m - q$

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.

Output Parameters

x11

The columns of `tril(x11)` specify reflectors for p_1 and the rows of `triu(x11, 1)` specify reflectors for q_1 , where `tril(A)` denotes the lower triangle of A , and `triu(A)` denotes the upper triangle of A .

x21

On exit, the columns of `tril(x21)` specify the reflectors for p_2

theta

REAL for sorbdb1

DOUBLE PRECISION for dorbdb1

COMPLEX for cunbdb1

DOUBLE COMPLEX for zunbdb1

Array, DIMENSION (q). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

phi

REAL for sorbdb1

DOUBLE PRECISION for dorbdb1

COMPLEX for cunbdb1

DOUBLE COMPLEX for zunbdb1

Array, DIMENSION ($q - 1$). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

taup1

REAL for sorbdb1

DOUBLE PRECISION for dorbdb1

COMPLEX for cunbdb1

DOUBLE COMPLEX for zunbdb1

	Array, DIMENSION (p).
	Scalar factors of the elementary reflectors that define p_1 .
<i>taup2</i>	REAL for sorbdb1 DOUBLE PRECISION for dorbdb1 COMPLEX for cunbdb1 DOUBLE COMPLEX for zunbdb1 Array, DIMENSION ($m-p$).
	Scalar factors of the elementary reflectors that define p_2 .
<i>tauq1</i>	REAL for sorbdb1 DOUBLE PRECISION for dorbdb1 COMPLEX for cunbdb1 DOUBLE COMPLEX for zunbdb1 Array, DIMENSION (q).
	Scalar factors of the elementary reflectors that define q_1 .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = $-i$, the i -th argument has an illegal value.

lwork

INTEGER. The size of the *work* array. $lwork \geq m-q$

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.

Output Parameters

x11

On exit: the columns of $\text{tril}(x11)$ specify reflectors for p_1 and the rows of $\text{triu}(x11, 1)$ specify reflectors for q_1 .

x21

On exit, the columns of $\text{tril}(x21)$ specify the reflectors for p_2

theta

REAL for sorbdb2

DOUBLE PRECISION for dorbdb2

COMPLEX for cunbdb2

Description

The routines `?orbdb3`/`?unbdb3` simultaneously bidiagonalize the blocks of a tall and skinny matrix X with orthonormal columns:

$$\begin{bmatrix} x_{11} \\ x_{21} \end{bmatrix} = \begin{bmatrix} p_1 & | & \\ \hline & p_2 & \end{bmatrix} \begin{bmatrix} b_{11} \\ 0 \\ b_{21} \\ 0 \end{bmatrix} q_1^T$$

The size of x_{11} is p by q , and x_{12} is $(m - p)$ by q . $m - p$ must not be larger than p , q , or $m - q$.

Tall and Skinny Matrix Routines

$q \leq \min(p, m - p, m - q)$	<code>?orbdb1</code> / <code>?unbdb1</code>
$p \leq \min(q, m - p, m - q)$	<code>?orbdb2</code> / <code>?unbdb2</code>
$m - p \leq \min(p, q, m - q)$	<code>?orbdb3</code> / <code>?unbdb3</code>
$m - q \leq \min(p, q, m - p)$	<code>?orbdb4</code> / <code>?unbdb4</code>

The orthogonal/unitary matrices p_1 , p_2 , and q_1 are p -by- p , $(m-p)$ -by- $(m-p)$, $(m-q)$ -by- $(m-q)$, respectively.

p_1 , p_2 , and q_1 are represented as products of elementary reflectors. See the description of `?orcsd2by1`/`?uncsd2by1` for details on generating p_1 , p_2 , and q_1 using `?orgqr` and `?orglq`.

The upper-bidiagonal matrices b_{11} and b_{12} of size $(m-p)$ by $(m-p)$ are represented implicitly by angles $\theta(1), \dots, \theta(q)$ and $\phi(1), \dots, \phi(q-1)$. Every entry in each bidiagonal band is a product of a sine or cosine of θ with a sine or cosine of ϕ . See [Sutton09] or the description of `?orcsd`/`?uncsd` for details.

Input Parameters

Description

The routines ?orbdb4/?unbdb4 simultaneously bidiagonalize the blocks of a tall and skinny matrix X with orthonormal columns:

$$\begin{bmatrix} x_{11} \\ x_{21} \end{bmatrix} = \begin{bmatrix} p_1 & | \\ \hline & p_2 \end{bmatrix} \begin{bmatrix} b_{11} \\ 0 \\ b_{21} \\ 0 \end{bmatrix} q_1^T$$

The size of x_{11} is p by q , and x_{12} is $(m - p)$ by q . $m - q$ must not be larger than q , p , or $m - p$.

Tall and Skinny Matrix Routines

$q \leq \min(p, m - p, m - q)$?orbdb1/?unbdb1
$p \leq \min(q, m - p, m - q)$?orbdb2/?unbdb2
$m - p \leq \min(p, q, m - q)$?orbdb3/?unbdb3
$m - q \leq \min(p, q, m - p)$?orbdb4/?unbdb4

The orthogonal/unitary matrices p_1 , p_2 , and q_1 are p -by- p , $(m - p)$ -by- $(m - p)$, $(m - q)$ -by- $(m - q)$, respectively.

p_1 , p_2 , and q_1 are represented as products of elementary reflectors. See the description of ?orcsd2by1/?uncsd2by1 for details on generating p_1 , p_2 , and q_1 using ?orgqr and ?orglq.

The upper-bidiagonal matrices b_{11} and b_{12} of size $(m - q)$ by $(m - q)$ are represented implicitly by angles $theta(1), \dots, theta(q)$ and $phi(1), \dots, phi(q - 1)$. Every entry in each bidiagonal band is a product of a sine or cosine of $theta$ with a sine or cosine of phi . See [Sutton09] or the description of ?orcsd/?uncsd for details.

Input Parameters

m	INTEGER. The number of rows in x_{11} plus the number of rows in x_{21} .
p	INTEGER. The number of rows in x_{11} . $0 \leq p \leq m$.
q	INTEGER. The number of columns in x_{11} and x_{21} . $0 \leq q \leq m$ and $0 \leq m - q \leq \min(p, m - p, q)$.
$x11$	REAL for sorbdb4 DOUBLE PRECISION for dorbdb4 COMPLEX for cunbdb4 DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($ldx11, q$).

On entry, the top block of the orthogonal/unitary matrix to be reduced.

$ldx11$

INTEGER. The leading dimension of the array X_{11} . $ldx11 \geq p$.

$x21$

REAL for sorbdb4

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($ldx21, q$).

On entry, the bottom block of the orthogonal/unitary matrix to be reduced.

$ldx21$

INTEGER. The leading dimension of the array X_{21} . $ldx21 \geq m - p$.

$work$

REAL for sorbdb4

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Workspace array, DIMENSION ($lwork$).

$lwork$

INTEGER. The size of the $work$ array. $lwork \geq m - q$

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

Output Parameters

$x11$

On exit: the columns of $\text{tril}(x11)$ specify reflectors for p_1 and the rows of $\text{triu}(x11, 1)$ specify reflectors for q_1 .

$x21$

On exit, the columns of $\text{tril}(x21)$ specify the reflectors for p_2

$theta$

REAL for sorbdb4

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (q). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles $theta$ and phi . See the Description section for details.

phi

REAL for sorbdb4

DOUBLE PRECISION for dorbdb4

COMPLEX for cunbdb4

DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($q-1$). The entries of bidiagonal blocks b_{11} and b_{21} can be computed from the angles *theta* and *phi*. See the Description section for details.

taup1

REAL for sorbdb4
DOUBLE PRECISION for dorbdb4
COMPLEX for cunbdb4
DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (p).

Scalar factors of the elementary reflectors that define p_1 .

taup2

REAL for sorbdb4
DOUBLE PRECISION for dorbdb4
COMPLEX for cunbdb4
DOUBLE COMPLEX for zunbdb4

Array, DIMENSION ($m-p$).

Scalar factors of the elementary reflectors that define p_2 .

tauq1

REAL for sorbdb4
DOUBLE PRECISION for dorbdb4
COMPLEX for cunbdb4
DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (q).

Scalar factors of the elementary reflectors that define q_1 .

phantom

REAL for sorbdb4
DOUBLE PRECISION for dorbdb4
COMPLEX for cunbdb4
DOUBLE COMPLEX for zunbdb4

Array, DIMENSION (m).

The routine computes an m -by-1 column vector y that is orthogonal to the columns of [*x11*; *x21*]. *phantom*(1: p) and *phantom*($p+1$: m) contain Householder vectors for y (1: p) and y ($p+1$: m), respectively.

info

Description

The routine ?org2r/?ung2r generates an m -by- n real/complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by ?geqrf.

Input Parameters

m INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n INTEGER. The number of columns of the matrix Q . $m \geq n \geq 0$.
k INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a REAL for sorg2r
 DOUBLE PRECISION for dorg2r

COMPLEX for `cung2r`

DOUBLE COMPLEX for `zung2r`.

Array, DIMENSION (*lda*, *n*).

On entry, the *i*-th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by `?geqrf` in the first *k* columns of its array argument *a*.

lda INTEGER. The first DIMENSION of the array *a*. $lda \geq \max(1, m)$.

tau REAL for `sorg2r`

DOUBLE PRECISION for `dorg2r`

COMPLEX for `cung2r`

DOUBLE COMPLEX for `zung2r`.

Array, DIMENSION (*k*).

tau(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by `?geqrf`.

work REAL for `sorg2r`

DOUBLE PRECISION for `dorg2r`

COMPLEX for `cung2r`

DOUBLE COMPLEX for `zung2r`.

Workspace array, DIMENSION (*n*).

Output Parameters

a On exit, the *m*-by-*n* matrix *Q*.

info INTEGER.

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument has an illegal value

?orgl2/?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorgl2( m, n, k, a, lda, tau, work, info )
```

```
call dorgl2( m, n, k, a, lda, tau, work, info )
```

```
call cungl2( m, n, k, a, lda, tau, work, info )
```

```
call zungl2( m, n, k, a, lda, tau, work, info )
```

Description

The routine ?orgr2/?ungr2 generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ for complex flavors as returned by ?gerqf.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $n \geq m$
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for sorgr2 DOUBLE PRECISION for dorgr2 COMPLEX for cungr2 DOUBLE COMPLEX for zungr2. Array, DIMENSION (lda, n). On entry, the ($m - k + i$)-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gerqf in the last k rows of its array argument a .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, m)$.
tau	REAL for sorgr2 DOUBLE PRECISION for dorgr2 COMPLEX for cungr2 DOUBLE COMPLEX for zungr2.

Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `?gerqf`.

work REAL for `sorgr2`
 DOUBLE PRECISION for `dorgr2`
 COMPLEX for `cungr2`
 DOUBLE COMPLEX for `zungr2`.
 Workspace array, DIMENSION (m).

Output Parameters

a On exit, the m -by- n matrix Q .
info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument has an illegal value

?orm2l/?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

- `mk1.fi`

Description

The routine `?orm2l/?unm2l` overwrites the general real/complex m -by- n matrix C with

Q^*C if *side* = 'L' and *trans* = 'N', or

Q^T*C / Q^H*C if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$C*Q$ if *side* = 'R' and *trans* = 'N', or

$C*Q^T / C*Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by `?geqlf`.

Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

side CHARACTER*1.

= 'L': apply Q or Q^T / Q^H from the left

= 'R': apply Q or Q^T / Q^H from the right

trans

CHARACTER*1.

= 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m

INTEGER. The number of rows of the matrix C . $m \geq 0$.

n

INTEGER. The number of columns of the matrix C . $n \geq 0$.

k

INTEGER. The number of elementary reflectors whose product defines the matrix Q .

If $side = 'L', m \geq k \geq 0$;

if $side = 'R', n \geq k \geq 0$.

a

REAL for sorm21

DOUBLE PRECISION for dorm21

COMPLEX for cunm21

DOUBLE COMPLEX for zunm21.

Array, DIMENSION (lda, k).

The i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqlf in the last k columns of its array argument a . The array a is modified by the routine but restored on exit.

lda

INTEGER. The leading dimension of the array a .

If $side = 'L', lda \geq \max(1, m)$

if $side = 'R', lda \geq \max(1, n)$.

tau

REAL for sorm21

DOUBLE PRECISION for dorm21

COMPLEX for cunm21

DOUBLE COMPLEX for zunm21.

Array, DIMENSION (k). $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.

c

REAL for sorm21

DOUBLE PRECISION for dorm21

COMPLEX for cunm21

DOUBLE COMPLEX for zunm21.

Array, DIMENSION (ldc, n).

On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array *C*. $ldc \geq \max(1, m)$.

work REAL for *sorm2l*
 DOUBLE PRECISION for *dorm2l*
 COMPLEX for *cunm2l*
 DOUBLE COMPLEX for *zunm2l*.

Workspace array, DIMENSION:
 (*n*) if *side* = 'L',
 (*m*) if *side* = 'R'.

Output Parameters

c On exit, *c* is overwritten by Q^*C or $Q^T C$ / $Q^H C$, or C^*Q , or C^*Q^T / C^*Q^H .

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

?orm2r/?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Include Files

<i>c</i>	On exit, <i>c</i> is overwritten by Q^*C or $Q^T C / Q^H C$, or C^*Q , or C^*Q^T / C^*Q^H .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value

?pbtf2

Computes the Cholesky factorization of a symmetric/Hermitian positive-definite band matrix (unblocked algorithm).

Syntax

```
call spbtf2( uplo, n, kd, ab, ldab, info )
call dpbtf2( uplo, n, kd, ab, ldab, info )
```

```
call cpbtf2( uplo, n, kd, ab, ldab, info )
```

```
call zpbtf2( uplo, n, kd, ab, ldab, info )
```

Include Files

- mkl.fi

Description

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite band matrix A .

The factorization has the form

$A = U^T * U$ for real flavors, $A = U^H * U$ for complex flavors if $uplo = 'U'$, or

$A = L * L^T$ for real flavors, $A = L * L^H$ for complex flavors if $uplo = 'L'$,

where U is an upper triangular matrix, and L is lower triangular. This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix A is stored: = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix A if $uplo = 'U'$, or the number of sub-diagonals if $uplo = 'L'$. $kd \geq 0$.
<i>ab</i>	REAL for spbtf2 DOUBLE PRECISION for dpbtf2 COMPLEX for cpbtf2 DOUBLE COMPLEX for zpbtf2. Array, DIMENSION (<i>ldab</i> , <i>n</i>). On entry, the upper or lower triangle of the symmetric/ Hermitian band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: if $uplo = 'U'$, $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if $uplo = 'L'$, $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> . $ldab \geq kd+1$.

Output Parameters

<i>ab</i>	On exit, If <i>info</i> = 0, the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A=U^T*U$ ($A=U^H*U$), or $A= L*L^T$ ($A = L*L^H$) of the band matrix <i>A</i> , in the same storage format as <i>A</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th argument had an illegal value > 0: if <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> is not positive definite, and the factorization could not be completed.

?potf2

Computes the Cholesky factorization of a symmetric/ Hermitian positive-definite matrix (unblocked algorithm).

Syntax

```
call spotf2( uplo, n, a, lda, info )
call dpotf2( uplo, n, a, lda, info )
call cspotf2( uplo, n, a, lda, info )
call zpotf2( uplo, n, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine ?potf2 computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite matrix *A*. The factorization has the form

$A = U^T*U$ for real flavors, $A = U^H*U$ for complex flavors if *uplo* = 'U', or

$A = L*L^T$ for real flavors, $A = L*L^H$ for complex flavors if *uplo* = 'L',

where *U* is an upper triangular matrix, and *L* is lower triangular.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#)

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix <i>A</i> is stored. = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>a</i>	REAL for spotf2 DOUBLE PRECISION for dpotf2

COMPLEX for `cpotf2`

DOUBLE COMPLEX for `zpotf2`.

Array, DIMENSION (*lda*, *n*).

On entry, the symmetric/Hermitian matrix *A*.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda

INTEGER. The leading dimension of the array *a*.

$lda \geq \max(1, n)$.

Output Parameters

a

On exit, If *info* = 0, the factor *U* or *L* from the Cholesky factorization $A = U^T * U$ ($A = U^H * U$), or $A = L * L^T$ ($A = L * L^H$).

info

INTEGER.

= 0: successful exit

< 0: if *info* = -*k*, the *k*-th argument had an illegal value

> 0: if *info* = *k*, the leading minor of order *k* is not positive definite, and the factorization could not be completed.

?ptts2

Solves a tridiagonal system of the form $A * X = B$ using the $L * D * L^H / L * D * L^H$ factorization computed by `?pttrf`.

Syntax

call `sptts2(n, nrhs, d, e, b, ldb)`

call `dptts2(n, nrhs, d, e, b, ldb)`

call `cptts2(iuplo, n, nrhs, d, e, b, ldb)`

call `zptts2(iuplo, n, nrhs, d, e, b, ldb)`

Include Files

- `mkl.fi`

Description

The routine `?ptts2` solves a tridiagonal system of the form

$$A * X = B$$

Real flavors `sptts2/dptts2` use the $L * D * L^T$ factorization of *A* computed by `spttrf/dpttrf`, and complex flavors `cptts2/zptts2` use the $U^H * D * U$ or $L * D * L^H$ factorization of *A* computed by `cpttrf/zpttrf`.

D is a diagonal matrix specified in the vector *d*, *U* (or *L*) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector *e*, and *X* and *B* are *n*-by-*nrhs* matrices.

Input Parameters

<i>iuplo</i>	<p>INTEGER. Used with complex flavors only.</p> <p>Specifies the form of the factorization, and whether the vector <i>e</i> is the superdiagonal of the upper bidiagonal factor <i>U</i> or the subdiagonal of the lower bidiagonal factor <i>L</i>.</p> <p>= 1: $A = U^H * D * U$, <i>e</i> is the superdiagonal of <i>U</i>;</p> <p>= 0: $A = L * D * L^H$, <i>e</i> is the subdiagonal of <i>L</i></p>
<i>n</i>	<p>INTEGER. The order of the tridiagonal matrix <i>A</i>. $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right hand sides, that is, the number of columns of the matrix <i>B</i>. $nrhs \geq 0$.</p>
<i>d</i>	<p>REAL for sptts2/cptts2</p> <p>DOUBLE PRECISION for dptts2/zptts2.</p> <p>Array, DIMENSION (<i>n</i>).</p> <p>The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the factorization of <i>A</i>.</p>
<i>e</i>	<p>REAL for sptts2</p> <p>DOUBLE PRECISION for dptts2</p> <p>COMPLEX for cptts2</p> <p>DOUBLE COMPLEX for zptts2.</p> <p>Array, DIMENSION (<i>n</i>-1).</p> <p>Contains the (<i>n</i>-1) subdiagonal elements of the unit bidiagonal factor <i>L</i> from the $L * D * L^T$ (for real flavors) or $L * D * L^H$ (for complex flavors when <i>iuplo</i> = 0) factorization of <i>A</i>.</p> <p>For complex flavors when <i>iuplo</i> = 1, <i>e</i> contains the (<i>n</i>-1) superdiagonal elements of the unit bidiagonal factor <i>U</i> from the factorization $A = U^H * D * U$.</p>
<i>B</i>	<p>REAL for sptts2/cptts2</p> <p>DOUBLE PRECISION for dptts2/zptts2.</p> <p>Array, DIMENSION (<i>ldb</i>, <i>nrhs</i>).</p> <p>On entry, the right hand side vectors <i>B</i> for the system of linear equations.</p>
<i>ldb</i>	<p>INTEGER. The leading dimension of the array <i>B</i>. $ldb \geq \max(1, n)$.</p>

Output Parameters

<i>b</i>	On exit, the solution vectors, <i>X</i> .
----------	---

?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call srscl( n, sa, sx, incx )
call drscl( n, sa, sx, incx )
call csrscl( n, sa, sx, incx )
call zdrscl( n, sa, sx, incx )
```

Include Files

- mkl.fi

Description

The routine `?rscl` multiplies an n -element real/complex vector x by the real scalar $1/a$. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Input Parameters

n	INTEGER. The number of components of the vector x .
sa	REAL for <code>srscl/csrscl</code> DOUBLE PRECISION for <code>drscl/zdrscl</code> . The scalar a which is used to divide each component of the vector x . sa must be ≥ 0 , or the subroutine will divide by zero.
sx	REAL for <code>srscl</code> DOUBLE PRECISION for <code>drscl</code> COMPLEX for <code>csrscl</code> DOUBLE COMPLEX for <code>zdrscl</code> . Array, DIMENSION $(1+(n-1)* incx)$. The n -element vector x .
$incx$	INTEGER. The increment between successive values of the vector sx . If $incx > 0$, $sx(1)=x(1)$, and $sx(1+(i-1)*incx)=x(i)$, $1 \leq i \leq n$.

Output Parameters

sx	On exit, the result x/a .
------	-----------------------------

?syswapr

Applies an elementary permutation on the rows and columns of a symmetric matrix.

Syntax

```
call ssyswapr( uplo, n, a, lda, i1, i2 )
call dsyswapr( uplo, n, a, lda, i1, i2 )
call csyswapr( uplo, n, a, lda, i1, i2 )
call zsyswapr( uplo, n, a, lda, i1, i2 )
```

```
call syswapr( a,i1,i2[,uplo] )
```

Include Files

- mkl.fi, lapack.f90

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates how the input matrix A has been factored:</p> <p>If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U*D*U^T$.</p> <p>If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L*D*L^T$.</p>
<i>n</i>	<p>INTEGER. The order of matrix A; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; $nrhs \geq 0$.</p>
<i>a</i>	<p>REAL for <code>ssyswapr</code></p> <p>DOUBLE PRECISION for <code>dsyswapr</code></p> <p>COMPLEX for <code>csyswapr</code></p> <p>DOUBLE COMPLEX for <code>zsyswapr</code></p> <p>Array of size (lda, n).</p> <p>The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?sytrf</code>.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array a. $lda \geq \max(1, n)$.</p>
<i>i1</i>	<p>INTEGER. Index of the first row to swap.</p>
<i>i2</i>	<p>INTEGER. Index of the second row to swap.</p>

Output Parameters

<i>a</i>	<p>If $info = 0$, the symmetric inverse of the original matrix.</p> <p>If $info = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.</p> <p>If $info = 'L'$, the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.</p>
----------	--

LAPACK 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [LAPACK 95 Interface Conventions](#).

Specific details for the routine `syswapr` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>i1</i>	Holds the index for swap.
<i>i2</i>	Holds the index for swap.
<i>uplo</i>	Indicates how the matrix <i>A</i> has been factored. Must be 'U' or 'L'.

See Also`?sytrf`**?sygs2/?hegs2**

Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).

Syntax

```
call ssygs2( itype, uplo, n, a, lda, b, ldb, info )
call dsygs2( itype, uplo, n, a, lda, b, ldb, info )
call chs2( itype, uplo, n, a, lda, b, ldb, info )
call zhegs2( itype, uplo, n, a, lda, b, ldb, info )
```

Include Files

- `mk1.fi`

Description

The routine `?sygs2/?hegs2` reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

If `itype = 1`, the problem is

$$A*x = \lambda*B*x$$

and A is overwritten by $\text{inv}(U^H)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^H)$ for complex flavors and by $\text{inv}(U^T)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^T)$ for real flavors.

If `itype = 2` or `3`, the problem is

$$A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x,$$

and A is overwritten by $U*A*U^H$ or L^H*A*L for complex flavors and by $U*A*U^T$ or L^T*A*L for real flavors. Here U^T and L^T are the transpose while U^H and L^H are conjugate transpose of U and L .

B must be previously factorized by `?potrf` as follows:

- U^H*U or $L*L^H$ for complex flavors
- U^T*U or $L*L^T$ for real flavors

Input Parameters

`itype` INTEGER.

For complex flavors:

= 1: compute $\text{inv}(U^H)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^H)$;

= 2 or 3: compute $U*A*U^H$ or L^H*A*L .

For real flavors:

= 1: compute $\text{inv}(U^T)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^T)$;

= 2 or 3: compute $U*A*U^T$ or L^T*A*L .

`uplo` CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored, and how B has been factorized.

= 'U': upper triangular

= 'L': lower triangular

n INTEGER. The order of the matrices *A* and *B*. $n \geq 0$.

a REAL for ssygs2
DOUBLE PRECISION for dsygs2
COMPLEX for chegs2
DOUBLE COMPLEX for zhegs2.

Array, DIMENSION (*lda*, *n*).

On entry, the symmetric/Hermitian matrix *A*.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER.

The leading dimension of the array *a*. $lda \geq \max(1, n)$.

b REAL for ssygs2
DOUBLE PRECISION for dsygs2
COMPLEX for chegs2
DOUBLE COMPLEX for zhegs2.

Array, DIMENSION (*ldb*, *n*).

The triangular factor from the Cholesky factorization of *B* as returned by ?potrf.

ldb INTEGER. The leading dimension of the array *b*. $ldb \geq \max(1, n)$.

Output Parameters

a On exit, If *info* = 0, the transformed matrix, stored in the same format as *A*.

info INTEGER.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?sytd2/?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation(unblocked algorithm).

Syntax

```
call ssytd2( uplo, n, a, lda, d, e, tau, info )
call dsytd2( uplo, n, a, lda, d, e, tau, info )
call chetd2( uplo, n, a, lda, d, e, tau, info )
call zhetd2( uplo, n, a, lda, d, e, tau, info )
```

Include Files

- mkl.fi

Description

The routine ?sytd2/?hetd2 reduces a real symmetric/complex Hermitian matrix A to real symmetric tridiagonal form T by an orthogonal/unitary similarity transformation: $Q^T A Q = T$ ($Q^H A Q = T$).

Input Parameters

uplo CHARACTER*1.
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored:
= 'U': upper triangular
= 'L': lower triangular

n INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for ssytd2
DOUBLE PRECISION for dsytd2
COMPLEX for chetd2
DOUBLE COMPLEX for zhetd2.
Array, DIMENSION (*lda*, *n*).
On entry, the symmetric/Hermitian matrix A .
If *uplo* = 'U', the leading n -by- n upper triangular part of *a* contains the upper triangular part of the matrix A , and the strictly lower triangular part of *a* is not referenced.
If *uplo* = 'L', the leading n -by- n lower triangular part of *a* contains the lower triangular part of the matrix A , and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, if *uplo* = 'U', the diagonal and first superdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if *uplo* = 'L', the diagonal and first subdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

d

REAL for ssytd2/chetd2
DOUBLE PRECISION for dsytd2/zhetd2.
Array, DIMENSION (*n*).

The diagonal elements of the tridiagonal matrix *T*:

$d(i) = a(i, i)$.

e

REAL for ssytd2/chetd2
DOUBLE PRECISION for dsytd2/zhetd2.
Array, DIMENSION (*n*-1).

The off-diagonal elements of the tridiagonal matrix *T*:

$e(i) = a(i, i+1)$ if *uplo* = 'U',

$e(i) = a(i+1, i)$ if *uplo* = 'L'.

tau

REAL for ssytd2
DOUBLE PRECISION for dsytd2
COMPLEX for chetd2
DOUBLE COMPLEX for zhetd2.
Array, DIMENSION (*n*).

The first *n*-1 elements contain scalar factors of the elementary reflectors. *tau*(*n*) is used as workspace.

info

INTEGER.
= 0: successful exit
< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?sytf2

Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2( uplo, n, a, lda, ipiv, info )
call dsytf2( uplo, n, a, lda, ipiv, info )
call csytf2( uplo, n, a, lda, ipiv, info )
call zsytf2( uplo, n, a, lda, ipiv, info )
```

Include Files

- mkl.fi

Description

The routine `?sytf2` computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U^T, \text{ or } A = L^* D^* L^T,$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored = 'U': upper triangular = 'L': lower triangular
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$.
<code>a</code>	REAL for <code>ssytf2</code> DOUBLE PRECISION for <code>dsytf2</code> COMPLEX for <code>csytf2</code> DOUBLE COMPLEX for <code>zsytf2</code> . Array, DIMENSION (lda, n). On entry, the symmetric matrix A . If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If <code>uplo</code> = 'L', the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.
<code>lda</code>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<code>a</code>	On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .
<code>ipiv</code>	INTEGER. Array, DIMENSION (n). Details of the interchanges and the block structure of D If <code>ipiv</code> (k) > 0, then rows and columns k and <code>ipiv</code> (k) are interchanged and $D(k,k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument has an illegal value

> 0: if $info = k$, $D(k,k)$ is exactly zero. The factorization are completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?sytf2_rook

Computes the factorization of a real/complex symmetric indefinite matrix, using the bounded Bunch-Kaufman diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2_rook( uplo, n, a, lda, ipiv, info )
```

```
call dsytf2_rook( uplo, n, a, lda, ipiv, info )
```

```
call csytf2_rook( uplo, n, a, lda, ipiv, info )
```

```
call zsytf2_rook( uplo, n, a, lda, ipiv, info )
```

Include Files

- mkl.fi

Description

The routine `?sytf2_rook` computes the factorization of a real/complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

$$A = U^* D^* U^T, \text{ or } A = L^* D^* L^T,$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

uplo

CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored

= 'U': upper triangular

= 'L': lower triangular

n

INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for ssytf2_rook
 DOUBLE PRECISION for dsytf2_rook
 COMPLEX for csytf2_rook
 DOUBLE COMPLEX for zsytf2_rook.
 Array, DIMENSION (*lda*, *n*).
 On entry, the symmetric matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER.
 The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L*.

ipiv INTEGER.
 Array, DIMENSION (*n*).
 Details of the interchanges and the block structure of *D*
 If *ipiv*(*k*) > 0, then rows and columns *k* and *ipiv*(*k*) were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.
 If *uplo* = 'U' and *ipiv*(*k*) < 0 and *ipiv*(*k* - 1) < 0, then rows and columns *k* and -*ipiv*(*k*) were interchanged, rows and columns *k* - 1 and -*ipiv*(*k* - 1) were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.
 If *uplo* = 'L' and *ipiv*(*k*) < 0 and *ipiv*(*k* + 1) < 0, then rows and columns *k* and -*ipiv*(*k*) were interchanged, rows and columns *k* + 1 and -*ipiv*(*k* + 1) were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*k*, the *k*-th argument has an illegal value
 > 0: if *info* = *k*, $D(k,k)$ is exactly zero. The factorization are completed, but the block diagonal matrix *D* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?hetf2

Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call chetf2( uplo, n, a, lda, ipiv, info )
call zhetf2( uplo, n, a, lda, ipiv, info )
```

Include Files

- mkl.fi

Description

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U^H \text{ or } A = L^* D^* L^H$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U^H is the conjugate transpose of U , and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>A</i>	COMPLEX for chetf2 DOUBLE COMPLEX for zhetf2. Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the Hermitian matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). Details of the interchanges and the block structure of D If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

?tgex2

Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.

Syntax

```
call stgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2, work,
            lwork, info )
```

```
call dtgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2, work,
            lwork, info )
```

```
call ctgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
```

```
call ztgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
```

Include Files

- `mk1.fi`

Description

The real routines `stgex2/dtgex2` swap adjacent diagonal blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (A, B) by an orthogonal equivalence transformation. (A, B) must be in generalized real Schur canonical form (as returned by `sgges/dgges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex routines `ctgex2/ztgex2` swap adjacent diagonal 1-by-1 blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) in an upper triangular matrix pair (A, B) by a unitary equivalence transformation.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

All routines optionally update the matrices Q and Z of generalized Schur vectors:

For real flavors,

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})^T = Q(\text{out}) * A(\text{out}) * Z(\text{out})^T$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})^T = Q(\text{out}) * B(\text{out}) * Z(\text{out})^T.$$

For complex flavors,

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})^H = Q(\text{out}) * A(\text{out}) * Z(\text{out})^H$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})^H = Q(\text{out}) * B(\text{out}) * Z(\text{out})^H.$$

Input Parameters

<code>wantq</code>	LOGICAL. If <code>wantq</code> = .TRUE. : update the left transformation matrix Q ; If <code>wantq</code> = .FALSE. : do not update Q .
<code>wantz</code>	LOGICAL. If <code>wantz</code> = .TRUE. : update the right transformation matrix Z ; If <code>wantz</code> = .FALSE. : do not update Z .
<code>n</code>	INTEGER. The order of the matrices A and B . $n \geq 0$.
<code>a, b</code>	REAL for <code>stgex2</code> DOUBLE PRECISION for <code>dtgex2</code> COMPLEX for <code>ctgex2</code> DOUBLE COMPLEX for <code>ztgex2</code> . Arrays, DIMENSION (lda, n) and (ldb, n), respectively. On entry, the matrices A and B in the pair (A, B) .
<code>lda</code>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The leading dimension of the array b . $ldb \geq \max(1, n)$.
<code>q, z</code>	REAL for <code>stgex2</code> DOUBLE PRECISION for <code>dtgex2</code> COMPLEX for <code>ctgex2</code> DOUBLE COMPLEX for <code>ztgex2</code> . Arrays, DIMENSION (ldq, n) and (ldz, n), respectively.

On entry, if *wantq* = `.TRUE.`, *q* contains the orthogonal/unitary matrix *Q*, and if *wantz* = `.TRUE.`, *z* contains the orthogonal/unitary matrix *Z*.

ldq INTEGER. The leading dimension of the array *q*. $ldq \geq 1$.
If *wantq* = `.TRUE.`, $ldq \geq n$.

ldz INTEGER. The leading dimension of the array *z*. $ldz \geq 1$.
If *wantz* = `.TRUE.`, $ldz \geq n$.

j1 INTEGER.
The index to the first block (*A11*, *B11*). $1 \leq j1 \leq n$.

n1 INTEGER. Used with real flavors only. The order of the first block (*A11*, *B11*). *n1* = 0, 1 or 2.

n2 INTEGER. Used with real flavors only. The order of the second block (*A22*, *B22*). *n2* = 0, 1 or 2.

work REAL for *stgex2*
DOUBLE PRECISION for *dtgex2*.
Workspace array, `DIMENSION(max(1, lwork))`. Used with real flavors only.

lwork INTEGER. The dimension of the array *work*.
 $lwork \geq \max(n * (n2 + n1), 2 * (n2 + n1)^2)$

Output Parameters

a On exit, the updated matrix *A*.

B On exit, the updated matrix *B*.

Q On exit, the updated matrix *Q*.
Not referenced if *wantq* = `.FALSE.`

z On exit, the updated matrix *Z*.
Not referenced if *wantz* = `.FALSE.`

info INTEGER.
=0: Successful exit For *stgex2*/*dtgex2*: If *info* = 1, the transformed matrix (*A*, *B*) would be too far from generalized Schur form; the blocks are not swapped and (*A*, *B*) and (*Q*, *Z*) are unchanged. The problem of swapping is too ill-conditioned. If *info* = -16: *lwork* is too small. Appropriate value for *lwork* is returned in *work*(1).
For *ctgex2*/*ztgex2*:
If *info* = 1, the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is ill-conditioned.

?tgsy2

Solves the generalized Sylvester equation (unblocked algorithm).

Syntax

```
call stgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, rdsum, rdscal, iwork, pq, info )

call dtgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, rdsum, rdscal, iwork, pq, info )

call ctgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, rdsum, rdscal, iwork, pq, info )

call ztgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, rdsum, rdscal, iwork, pq, info )
```

Include Files

- mkl.fi

Description

The routine ?tgsy2 solves the generalized Sylvester equation:

$$A^*R - L^*B = \text{scale} * C \quad (1)$$

$$D^*R - L^*E = \text{scale} * F$$

using Level 1 and 2 BLAS, where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively. For `stgsy2/dtgsy2`, pairs (A, D) and (B, E) must be in generalized Schur canonical form, that is, A, B are upper quasi triangular and D, E are upper triangular. For `ctgsy2/ztgsy2`, matrices A, B, D and E are upper triangular (that is, (A, D) and (B, E) in generalized Schur form).

The solution (R, L) overwrites (C, F) .

$0 \leq \text{scale} \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation, solving equation (1) corresponds to solve

$$Z * x = \text{scale} * b$$

where Z is defined for real flavors as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B^T, I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E^T, I_m) \end{bmatrix} \quad (2)$$

and for complex flavors as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B^H, I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E^H, I_m) \end{bmatrix} \quad (3)$$

Here I_k is the identity matrix of size k and X^T (X^H) is the transpose (conjugate transpose) of X . $\text{kron}(X, Y)$ denotes the Kronecker product between the matrices X and Y .

For real flavors, if $trans = 'T'$, solve the transposed system

$$Z^T * y = scale * b$$

for y , which is equivalent to solving for R and L in

$$A^T * R + D^T * L = scale * C \quad (4)$$

$$R * B^T + L * E^T = scale * (-F)$$

For complex flavors, if $trans = 'C'$, solve the conjugate transposed system

$$Z^H * y = scale * b$$

for y , which is equivalent to solving for R and L in

$$A^H * R + D^H * L = scale * C \quad (5)$$

$$R * B^H + L * E^H = scale * (-F)$$

These cases are used to compute an estimate of $\text{Dif}[(A, D), (B, E)] = \text{sigma_min}(Z)$ using reverse communication with [?lacon](#).

[?tgssy2](#) also (for $ijob \geq 1$) contributes to the computation in [?tgssy1](#) of an upper bound on the separation between two matrix pairs. Then the input (A, D) , (B, E) are sub-pencils of the matrix pair (two matrix pairs) in [?tgssy1](#). See [?tgssy1](#) for details.

Input Parameters

$trans$	<p>CHARACTER*1.</p> <p>If $trans = 'N'$, solve the generalized Sylvester equation (1);</p> <p>If $trans = 'T'$: solve the transposed system (4).</p> <p>If $trans = 'C'$: solve the conjugate transposed system (5).</p>
$ijob$	<p>INTEGER. Specifies what kind of functionality is to be performed.</p> <p>If $ijob = 0$: solve (1) only.</p> <p>If $ijob = 1$: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (look ahead strategy is used);</p> <p>If $ijob = 2$: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (?gecon on sub-systems is used).</p> <p>Not referenced if $trans = 'T'$.</p>
m	<p>INTEGER. On entry, m specifies the order of A and D, and the row dimension of C, F, R and L.</p>
n	<p>INTEGER. On entry, n specifies the order of B and E, and the column dimension of C, F, R and L.</p>
a, b	<p>REAL for stgssy2</p> <p>DOUBLE PRECISION for dtgssy2</p> <p>COMPLEX for ctgssy2</p> <p>DOUBLE COMPLEX for ztgssy2.</p>

Arrays, DIMENSION (lda, m) and (ldb, n) , respectively. On entry, a contains an upper (quasi) triangular matrix A , and b contains an upper (quasi) triangular matrix B .

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, m)$.

ldb INTEGER.

The leading dimension of the array b . $ldb \geq \max(1, n)$.

c, f REAL for stgsy2
DOUBLE PRECISION for dtgsy2
COMPLEX for ctgsy2
DOUBLE COMPLEX for ztgsy2.

Arrays, DIMENSION (ldc, n) and (ldf, n) , respectively. On entry, c contains the right-hand-side of the first matrix equation in (1), and f contains the right-hand-side of the second matrix equation in (1).

ldc INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.

d, e REAL for stgsy2
DOUBLE PRECISION for dtgsy2
COMPLEX for ctgsy2
DOUBLE COMPLEX for ztgsy2.

Arrays, DIMENSION (ldd, m) and (lde, n) , respectively. On entry, d contains an upper triangular matrix D , and e contains an upper triangular matrix E .

ldd INTEGER. The leading dimension of the array d . $ldd \geq \max(1, m)$.

lde INTEGER. The leading dimension of the array e . $lde \geq \max(1, n)$.

ldf INTEGER. The leading dimension of the array f . $ldf \geq \max(1, m)$.

$rdsum$ REAL for stgsy2/ctgsy2
DOUBLE PRECISION for dtgsy2/ztgsy2.

On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ?tgsyL, where the scaling factor $rdscal$ has been factored out.

$rdscal$ REAL for stgsy2/ctgsy2
DOUBLE PRECISION for dtgsy2/ztgsy2.

On entry, scaling factor used to prevent overflow in $rdsum$.

$iwork$ INTEGER. Used with real flavors only.

Workspace array, DIMENSION $(m+n+2)$.

Output Parameters

c On exit, if $ijob = 0$, c is overwritten by the solution R .

<i>f</i>	On exit, if <i>ijob</i> = 0, <i>f</i> is overwritten by the solution <i>L</i> .
<i>scale</i>	REAL for stgsy2/ctgsy2 DOUBLE PRECISION for dtgsy2/ztgsy2. On exit, $0 \leq scale \leq 1$. If $0 < scale < 1$, the solutions <i>R</i> and <i>L</i> (<i>C</i> and <i>F</i> on entry) hold the solutions to a slightly perturbed system, but the input matrices <i>A</i> , <i>B</i> , <i>D</i> and <i>E</i> are not changed. If <i>scale</i> = 0, <i>R</i> and <i>L</i> hold the solutions to the homogeneous system with <i>C</i> = <i>F</i> = 0. Normally <i>scale</i> = 1.
<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = 'T', <i>rdsum</i> is not touched. Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsyl.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched. Note that <i>rdscal</i> only makes sense when ?tgsy2 is called by ?tgsyl.
<i>pq</i>	INTEGER. Used with real flavors only. On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by the routine stgsy2/dtgsy2.
<i>info</i>	INTEGER. On exit, if <i>info</i> is set to = 0: Successful exit < 0: If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument has an illegal value. > 0: The matrix pairs (<i>A</i> , <i>D</i>) and (<i>B</i> , <i>E</i>) have common or very close eigenvalues.

?trti2

Computes the inverse of a triangular matrix (unblocked algorithm).

Syntax

```
call strti2( uplo, diag, n, a, lda, info )
call dtrti2( uplo, diag, n, a, lda, info )
call ctrti2( uplo, diag, n, a, lda, info )
call ztrti2( uplo, diag, n, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine ?trti2 computes the inverse of a real/complex upper or lower triangular matrix.

This is the *Level 2 BLAS* version of the algorithm.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix <i>A</i> is unit triangular. = 'N': non-unit triangular = 'N': non-unit triangular
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>a</i>	REAL for <i>strti2</i> DOUBLE PRECISION for <i>dtrti2</i> COMPLEX for <i>ctrti2</i> DOUBLE COMPLEX for <i>ztrti2</i> . Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced. If <i>diag</i> = 'U', the diagonal elements of <i>a</i> are also not referenced and are assumed to be 1.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, the (triangular) inverse of the original matrix, in the same storage format.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>k</i> , the <i>k</i> -th argument had an illegal value

clag2z

Converts a complex single precision matrix to a complex double precision matrix.

Syntax

call clag2z(*m*, *n*, *sa*, *lds*, *a*, *lda*, *info*)

Include Files

- `mkl.fi`

Description

This routine converts a complex single precision matrix *SA* to a complex double precision matrix *A*.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>lds</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $lds \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>lds</i> , <i>n</i>). On exit, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

dlag2s

Converts a double precision matrix to a single precision matrix.

Syntax

```
call dlag2s( m, n, a, lda, sa, lds, info )
```

Include Files

- `mkl.fi`

Description

This routine converts a double precision matrix *SA* to a single precision matrix *A*.

RMAX is the overflow for the single precision arithmetic. `dlag2s` checks that all the entries of *A* are between $-RMAX$ and *RMAX*. If not, the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in the matrix A ($n \geq 0$).
a	DOUBLE PRECISION array, DIMENSION (lda, n). On entry, contains the m -by- n coefficient matrix A .
lda	INTEGER. The leading dimension of the array a ; $lda \geq \max(1, m)$.
$ldsa$	INTEGER. The leading dimension of the array sa ; $ldsa \geq \max(1, m)$.

Output Parameters

sa	REAL array, DIMENSION ($ldsa, n$). On exit, if $info = 0$, contains the m -by- n coefficient matrix SA ; if $info > 0$, the content of sa is unspecified.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = 1$, an entry of the matrix A is greater than the single precision overflow threshold; in this case, the content of sa on exit is unspecified.

slag2d

Converts a single precision matrix to a double precision matrix.

Syntax

```
call slag2d( m, n, sa, ldsa, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine converts a single precision matrix SA to a double precision matrix A .

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is an auxiliary routine so there is no argument checking.

Input Parameters

m	INTEGER. The number of lines of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in the matrix A ($n \geq 0$).
sa	REAL array, DIMENSION ($ldsa, n$). On entry, contains the m -by- n coefficient matrix SA .

ldsa INTEGER. The leading dimension of the array *sa*; $ldsa \geq \max(1, m)$.

lda INTEGER. The leading dimension of the array *a*; $lda \geq \max(1, m)$.

Output Parameters

a DOUBLE PRECISION array, DIMENSION (*lda*, *n*).
On exit, contains the *m*-by-*n* coefficient matrix *A*.

info INTEGER.
If *info* = 0, the execution is successful.

zlag2c

Converts a complex double precision matrix to a complex single precision matrix.

Syntax

```
call zlag2c( m, n, a, lda, sa, ldsa, info )
```

Include Files

- mkl.fi

Description

The routine converts a double precision complex matrix *SA* to a single precision complex matrix *A*.

RMAX is the overflow for the single precision arithmetic. *zlag2c* checks that all the entries of *A* are between -RMAX and RMAX. If not, the conversion is aborted and a flag is raised.

This is an auxiliary routine so there is no argument checking.

Input Parameters

m INTEGER. The number of lines of the matrix *A* ($m \geq 0$).

n INTEGER. The number of columns in the matrix *A* ($n \geq 0$).

a DOUBLE COMPLEX array, DIMENSION (*lda*, *n*).
On entry, contains the *m*-by-*n* coefficient matrix *A*.

lda INTEGER. The leading dimension of the array *a*; $lda \geq \max(1, m)$.

ldsa INTEGER. The leading dimension of the array *sa*; $ldsa \geq \max(1, m)$.

Output Parameters

sa COMPLEX array, DIMENSION (*ldsa*, *n*).
On exit, if *info* = 0, contains the *m*-by-*n* coefficient matrix *SA*; if *info* > 0, the content of *sa* is unspecified.

info INTEGER.
If *info* = 0, the execution is successful.

If *info* = 1, an entry of the matrix *A* is greater than the single precision overflow threshold; in this case, the content of *sa* on exit is unspecified.

?larfp

Generates a real or complex elementary reflector.

Syntax

```
call slarfp(n, alpha, x, incx, tau)
call dlarfp(n, alpha, x, incx, tau)
call clarfp(n, alpha, x, incx, tau)
call zlarfp(n, alpha, x, incx, tau)
```

Include Files

- mkl.fi

Description

The ?larfp routines generate a real or complex elementary reflector *H* of order *n*, such that

$$H \begin{pmatrix} \alpha \\ x \end{pmatrix} = \begin{pmatrix} \beta \\ 0 \end{pmatrix},$$

and $H^*H = I$ for real flavors, $\text{conjg}(H)^*H = I$ for complex flavors.

Here

alpha and *beta* are scalars, *beta* is real and non-negative,

x is (*n*-1)-element vector.

H is represented in the form

$$H = I - \tau \begin{pmatrix} 1 \\ v \end{pmatrix} \begin{pmatrix} 1 & v' \end{pmatrix},$$

where *tau* is scalar, and *v* is (*n*-1)-element vector .

For real flavors if the elements of *x* are all zero, then *tau* = 0 and *H* is taken to be the unit matrix. Otherwise $1 \leq \tau \leq 2$.

For complex flavors if the elements of *x* are all zero and *alpha* is real, then *tau* = 0 and *H* is taken to be the unit matrix. Otherwise $1 \leq \text{real}(\tau) \leq 2$, and $|\text{abs}(\tau) - 1| \leq 1$.

Input Parameters

<i>n</i>	INTEGER. Specifies the order of the elementary reflector.
<i>alpha</i>	REAL for slarfp DOUBLE PRECISION for dlarfp COMPLEX for clarfp DOUBLE COMPLEX for zlarfp Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for slarfp

DOUBLE PRECISION for dlarfp

COMPLEX for clarfp

DOUBLE COMPLEX for zlarfp

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. It contains the vector x .

incx

INTEGER. Specifies the increment for the elements of x .

The value of *incx* must not be zero.

Output Parameters

alpha

Overwritten by the value *beta*.

y

Overwritten by the vector v .

tau

REAL for slarfp

DOUBLE PRECISION for dlarfp

COMPLEX for clarfp

DOUBLE COMPLEX for zlarfp

Contains the scalar *tau*.

ila?lc

Scans a matrix for its last non-zero column.

Syntax

value = ilaslc(*m*, *n*, *a*, *lda*)

value = iladlc(*m*, *n*, *a*, *lda*)

value = ilaclc(*m*, *n*, *a*, *lda*)

value = ilazlc(*m*, *n*, *a*, *lda*)

Include Files

- mkl.fi

Description

The *ila?lc* routines scan a matrix A for its last non-zero column.

Input Parameters

m

INTEGER. Specifies number of rows in the matrix A .

n

INTEGER. Specifies number of columns in the matrix A .

a

REAL for ilaslc

DOUBLE PRECISION for iladlc

COMPLEX for ilaclc

DOUBLE COMPLEX for `ilazlc`

Array, DIMENSION(`lda`, *). The second dimension of *a* must be at least $\max(1, n)$.

Before entry the leading *n*-by-*n* part of the array *a* must contain the matrix *A*.

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, m)$.

Output Parameters

value

INTEGER

Number of the last non-zero column.

ila?lr

Scans a matrix for its last non-zero row.

Syntax

`value = ilaslr(m, n, a, lda)`

`value = iladlr(m, n, a, lda)`

`value = ilaclr(m, n, a, lda)`

`value = ilazlr(m, n, a, lda)`

Include Files

- `mkl.fi`

Description

The `ila?lr` routines scan a matrix *A* for its last non-zero row.

Input Parameters

m

INTEGER. Specifies number of rows in the matrix *A*.

n

INTEGER. Specifies number of columns in the matrix *A*.

a

REAL for `ilaslr`

DOUBLE PRECISION for `iladlr`

COMPLEX for `ilaclr`

DOUBLE COMPLEX for `idazlr`

Array, DIMENSION(`lda`, *). The second dimension of *a* must be at least $\max(1, n)$.

Before entry the leading *n*-by-*n* part of the array *a* must contain the matrix *A*.

lda

INTEGER. Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, m)$.

	DOUBLE PRECISION for dgsvj0.
	Arrays, DIMENSION (n). Contains the diagonal matrix D that accumulates the scaling factors from the fast scaled Jacobi rotations. On entry $A*\text{diag}(D)$ represents the input matrix.
<i>sva</i>	REAL for sgsvj0 DOUBLE PRECISION for dgsvj0.
	Arrays, DIMENSION (n). Contains the Euclidean norms of the columns of the matrix $A*\text{diag}(D)$.
<i>mv</i>	INTEGER. The leading dimension of b ; at least $\max(1, p)$. If $jobv = 'A'$, then mv rows of v are post-multiplied by a sequence of Jacobi rotations. If $jobv = 'N'$, then mv is not referenced.
<i>v</i>	REAL for sgsvj0 DOUBLE PRECISION for dgsvj0. Array, DIMENSION ($ldv, *$). The second dimension of a must be at least $\max(1, n)$. If $jobv = 'V'$, then n rows of v are post-multiplied by a sequence of Jacobi rotations. If $jobv = 'A'$, then mv rows of v are post-multiplied by a sequence of Jacobi rotations. If $jobv = 'N'$, then v is not referenced.
<i>ldv</i>	INTEGER. The leading dimension of the array v ; $ldv \geq 1$ $ldv \geq n$ if $jobv = 'V'$; $ldv \geq mv$ if $jobv = 'A'$.
<i>eps</i>	REAL for sgsvj0 DOUBLE PRECISION for dgsvj0. The relative machine precision (epsilon) returned by the routine ?lamch .
<i>sfmin</i>	REAL for sgsvj0 DOUBLE PRECISION for dgsvj0. Value of safe minimum returned by the routine ?lamch .
<i>tol</i>	REAL for sgsvj0 DOUBLE PRECISION for dgsvj0. The threshold for Jacobi rotations. For a pair $A(:, p), A(:, q)$ of pivot columns, the Jacobi rotation is applied only if $\text{abs}(\cos(\text{angle}(A(:, p), A(:, q)))) > \text{tol}$.
<i>nsweep</i>	INTEGER. The number of sweeps of Jacobi rotations to be performed.

work REAL for sgsvj0
DOUBLE PRECISION for dgsvj0.
Workspace array, DIMENSION (*lwork*).

lwork INTEGER. The size of the array *work*; at least $\max(1, m)$.

Output Parameters

a On exit, $A \cdot \text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in *tol* and *nsweep*, respectively

d On exit, $A \cdot \text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in *tol* and *nsweep*, respectively.

sva On exit, contains the Euclidean norms of the columns of the output matrix $A \cdot \text{diag}(D)$.

v If *jobv* = 'V', then *n* rows of *v* are post-multiplied by a sequence of Jacobi rotations.
If *jobv* = 'A', then *mv* rows of *v* are post-multiplied by a sequence of Jacobi rotations.
If *jobv* = 'N', then *v* is not referenced.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

?gsvj1

Pre-processor for the routine ?gesvj, applies Jacobi rotations targeting only particular pivots.

Syntax

call sgsvj1(*jobv*, *m*, *n*, *nl*, *a*, *lda*, *d*, *sva*, *mv*, *v*, *ldv*, *eps*, *sfmin*, *tol*, *nsweep*, *work*, *lwork*, *info*)

call dgsvj1(*jobv*, *m*, *n*, *nl*, *a*, *lda*, *d*, *sva*, *mv*, *v*, *ldv*, *eps*, *sfmin*, *tol*, *nsweep*, *work*, *lwork*, *info*)

Include Files

- mkl.fi

Description

T

This routine is called from ?gesvj as a pre-processor and that is its main purpose. It applies Jacobi rotations in the same way as ?gesvj does, but it targets only particular pivots and it does not check convergence (stopping criterion).

The routine `?gsvj1` applies few sweeps of Jacobi rotations in the column space of the input m -by- n matrix A . The pivot pairs are taken from the (1,2) off-diagonal block in the corresponding n -by- n Gram matrix A^*A . The block-entries (*tiles*) of the (1,2) off-diagonal block are marked by the `[x]`'s in the following scheme:

```
| *  *  *  [x] [x] [x] |
| *  *  *  [x] [x] [x] |
| *  *  *  [x] [x] [x] |
| [x] [x] [x] *  *  *  |
| [x] [x] [x] *  *  *  |
| [x] [x] [x] *  *  *  |
```

row-cycling in the nbl_r -by- $nbl_c[x]$ blocks, row-cyclic pivoting inside each `[x]` block

In terms of the columns of the matrix A , the first $n1$ columns are rotated 'against' the remaining $n-n1$ columns, trying to increase the angle between the corresponding subspaces. The off-diagonal block is $n1$ -by- $(n-n1)$ and it is tiled using quadratic tiles. The number of sweeps is specified by `nsweep`, and the orthogonality threshold is set by `tol`.

Input Parameters

<code>jobv</code>	CHARACTER*1. Must be 'V', 'A', or 'N'. Specifies whether the output from this routine is used to compute the matrix V . If <code>jobv = 'V'</code> , the product of the Jacobi rotations is accumulated by post-multiplying the n -by- n array v . If <code>jobv = 'A'</code> , the product of the Jacobi rotations is accumulated by post-multiplying the m -by- n array v . If <code>jobv = 'N'</code> , the Jacobi rotations are not accumulated.
<code>m</code>	INTEGER. The number of rows of the input matrix A ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns of the input matrix B ($m \geq n \geq 0$).
<code>n1</code>	INTEGER. Specifies the 2-by-2 block partition. The first $n1$ columns are rotated 'against' the remaining $n-n1$ columns of the matrix A .
<code>a</code>	REAL for <code>sgsvj1</code> DOUBLE PRECISION for <code>dgsvj1</code> . Arrays, DIMENSION (<code>lda</code> , *). Contains the m -by- n matrix A , such that $A \cdot \text{diag}(D)$ represents the input matrix. The second dimension of <code>a</code> must be at least $\max(1, n)$.
<code>lda</code>	INTEGER. The leading dimension of <code>a</code> ; at least $\max(1, m)$.
<code>d</code>	REAL for <code>sgsvj1</code> DOUBLE PRECISION for <code>dgsvj1</code> . Arrays, DIMENSION (n). Contains the diagonal matrix D that accumulates the scaling factors from the fast scaled Jacobi rotations. On entry $A \cdot \text{diag}(D)$ represents the input matrix.
<code>sva</code>	REAL for <code>sgsvj1</code> DOUBLE PRECISION for <code>dgsvj1</code> .

	<p>Arrays, <code>DIMENSION (n)</code>. Contains the Euclidean norms of the columns of the matrix $A * \text{diag}(D)$.</p>
<i>mv</i>	<p>INTEGER. The leading dimension of <i>b</i>; at least $\max(1, p)$.</p> <p>If <i>jobv</i> = 'A', then <i>mv</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations.</p> <p>If <i>jobv</i> = 'N', then <i>mv</i> is not referenced .</p>
<i>v</i>	<p>REAL for <code>sgsvj1</code></p> <p>DOUBLE PRECISION for <code>dgsvj1</code>.</p> <p>Array, <code>DIMENSION (ldv, *)</code>. The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p>If <i>jobv</i> = 'V', then <i>n</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations.</p> <p>If <i>jobv</i> = 'A', then <i>mv</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations.</p> <p>If <i>jobv</i> = 'N', then <i>v</i> is not referenced.</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i>; $ldv \geq 1$</p> <p>$ldv \geq n$ if <i>jobv</i> = 'V';</p> <p>$ldv \geq mv$ if <i>jobv</i> = 'A'.</p>
<i>eps</i>	<p>REAL for <code>sgsvj1</code></p> <p>DOUBLE PRECISION for <code>dgsvj1</code>.</p> <p>The relative machine precision (epsilon) returned by the routine ?lamch.</p>
<i>sfmin</i>	<p>REAL for <code>sgsvj1</code></p> <p>DOUBLE PRECISION for <code>dgsvj1</code>.</p> <p>Value of safe minimum returned by the routine ?lamch.</p>
<i>tol</i>	<p>REAL for <code>sgsvj1</code></p> <p>DOUBLE PRECISION for <code>dgsvj1</code>.</p> <p>The threshold for Jacobi rotations. For a pair $A(:, p), A(:, q)$ of pivot columns, the Jacobi rotation is applied only if $\text{abs}(\cos(\text{angle}(A(:, p), A(:, q)))) > \text{tol}$.</p>
<i>nsweep</i>	<p>INTEGER.</p> <p>The number of sweeps of Jacobi rotations to be performed.</p>
<i>work</i>	<p>REAL for <code>sgsvj1</code></p> <p>DOUBLE PRECISION for <code>dgsvj1</code>.</p> <p>Workspace array, <code>DIMENSION (lwork)</code>.</p>
<i>lwork</i>	<p>INTEGER. The size of the array <i>work</i>; at least $\max(1, m)$.</p>

Output Parameters

<i>a</i>	On exit, $A * \text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in <i>tol</i> and <i>nsweep</i> , respectively
<i>d</i>	On exit, $A * \text{diag}(D)$ represents the input matrix post-multiplied by a sequence of Jacobi rotations, where the rotation threshold and the total number of sweeps are given in <i>tol</i> and <i>nsweep</i> , respectively.
<i>sva</i>	On exit, contains the Euclidean norms of the columns of the output matrix $A * \text{diag}(D)$.
<i>v</i>	<p>If <i>jobv</i> = 'V', then <i>n</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations.</p> <p>If <i>jobv</i> = 'A', then <i>mv</i> rows of <i>v</i> are post-multiplied by a sequence of Jacobi rotations.</p> <p>If <i>jobv</i> = 'N', then <i>v</i> is not referenced.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

?sfrk

Performs a symmetric rank-*k* operation for matrix in RFP format.

Syntax

```
call ssfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
call dsfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
```

Include Files

- mkl.fi

Description

The ?sfrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha A A^T + \beta C,$$

or

$$C := \alpha A^T A + \beta C,$$

where:

alpha and *beta* are scalars,

C is an *n*-by-*n* symmetric matrix in [rectangular full packed \(RFP\) format](#),

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

<i>transr</i>	<p>CHARACTER*1.</p> <p>if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>C</i> is stored;</p> <p>if <i>transr</i> = 'T' or 't', the transpose form of RFP <i>C</i> is stored.</p>
<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * A^T + \beta * C$;</p> <p>if <i>trans</i> = 'T' or 't', then $C := \alpha * A^T * A + \beta * C$;</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i>, and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the matrix <i>A</i>.</p> <p>The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>REAL for ssfrk</p> <p>DOUBLE PRECISION for dsfrk</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>REAL for ssfrk</p> <p>DOUBLE PRECISION for dsfrk</p> <p>Array, DIMENSION(<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>beta</i>	<p>REAL for ssfrk</p> <p>DOUBLE PRECISION for dsfrk</p> <p>Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>REAL for ssfrk</p> <p>DOUBLE PRECISION for dsfrk</p> <p>Array, size $(n * (n + 1) / 2)$. Before entry contains the symmetric matrix <i>C</i> in RFP format.</p>

Output Parameters

c If *trans* = 'N' or 'n', then *c* contains $C := \alpha * A * A' + \beta * C$;
 if *trans* = 'T' or 't', then *c* contains $C := \alpha * A' * A + \beta * C$;

?hfrk

Performs a Hermitian rank-*k* operation for matrix in RFP format.

Syntax

```
call chfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
call zhfrk(transr, uplo, trans, n, k, alpha, a, lda, beta, c)
```

Include Files

- mkl.fi

Description

The ?hfrk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * A^H + \beta * C,$$

or

$$C := \alpha * A^H * A + \beta * C,$$

where:

alpha and *beta* are real scalars,

C is an *n*-by-*n* Hermitian matrix in [RFP format](#),

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

transr CHARACTER*1.
 if *transr* = 'N' or 'n', the normal form of RFP *C* is stored;
 if *transr* = 'C' or 'c', the conjugate-transpose form of RFP *C* is stored.

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the array *c* is used.
 If *uplo* = 'U' or 'u', then the upper triangular part of the array *c* is used.
 If *uplo* = 'L' or 'l', then the low triangular part of the array *c* is used.

trans CHARACTER*1. Specifies the operation:
 if *trans* = 'N' or 'n', then $C := \alpha * A * A^H + \beta * C$;
 if *trans* = 'C' or 'c', then $C := \alpha * A^H * A + \beta * C$.

n INTEGER. Specifies the order of the matrix *C*. The value of *n* must be at least zero.

<i>k</i>	<p>INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i>, and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i>.</p> <p>The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for chfrk</p> <p>DOUBLE COMPLEX for zhfrk</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>COMPLEX for chfrk</p> <p>DOUBLE COMPLEX for zhfrk</p> <p>Array, DIMENSION(<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>beta</i>	<p>COMPLEX for chfrk</p> <p>DOUBLE COMPLEX for zhfrk</p> <p>Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>COMPLEX for chfrk</p> <p>DOUBLE COMPLEX for zhfrk</p> <p>Array, size $(n*(n+1)/2)$. Before entry contains the Hermitian matrix <i>C</i> in in RFP format.</p>

Output Parameters

<i>c</i>	<p>If <i>trans</i> = 'N' or 'n', then <i>c</i> contains $C := \alpha * A * A^H + \beta * C$;</p> <p>if <i>trans</i> = 'C' or 'c', then <i>c</i> contains $C := \alpha * A^H * A + \beta * C$;</p>
----------	---

?tfsm

Solves a matrix equation (one operand is a triangular matrix in RFP format).

Syntax

```
call stfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call dtfsm(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call ctfsf(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
call ztfsf(transr, side, uplo, trans, diag, m, n, alpha, a, b, ldb)
```

Include Files

- mkl.fi

Description

The `?tfsm` routines solve one of the following matrix equations:

$$\text{op}(A) * X = \alpha * B,$$

or

$$X * \text{op}(A) = \alpha * B,$$

where:

α is a scalar,

X and B are m -by- n matrices,

A is a unit, or non-unit, upper or lower triangular matrix in [rectangular full packed \(RFP\) format](#).

$\text{op}(A)$ can be one of the following:

- $\text{op}(A) = A$ or $\text{op}(A) = A^T$ for real flavors
- $\text{op}(A) = A$ or $\text{op}(A) = A^H$ for complex flavors

The matrix B is overwritten by the solution matrix X .

Input Parameters

<i>transr</i>	CHARACTER*1. if <i>transr</i> = 'N' or 'n', the normal form of RFP A is stored; if <i>transr</i> = 'T' or 't', the transpose form of RFP A is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP A is stored.
<i>side</i>	CHARACTER*1. Specifies whether $\text{op}(A)$ appears on the left or right of X in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(A) * X = \alpha * B$; if <i>side</i> = 'R' or 'r', then $X * \text{op}(A) = \alpha * B$.
<i>uplo</i>	CHARACTER*1. Specifies whether the RFP matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>trans</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>trans</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>trans</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>diag</i>	CHARACTER*1. Specifies whether the RFP matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	INTEGER. Specifies the number of rows of B . The value of m must be at least zero.

<i>n</i>	INTEGER. Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Specifies the scalar <i>alpha</i>.</p> <p>When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.</p>
<i>a</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Array, size $(n*(n+1)/2)$. Contains the matrix <i>A</i> in RFP format.</p>
<i>b</i>	<p>REAL for stfsm</p> <p>DOUBLE PRECISION for dtfsm</p> <p>COMPLEX for ctfsm</p> <p>DOUBLE COMPLEX for ztfsm</p> <p>Array, size $(1, ldb*n)$</p> <p>Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the right-hand side matrix <i>B</i>.</p>
<i>ldb</i>	INTEGER. Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
----------	---

?lansf

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix in RFP format.

Syntax

```
val = slansf(norm, transr, uplo, n, a, work)
```

```
val = dlansf(norm, transr, uplo, n, a, work)
```

Include Files

- mkl.fi

Description

T

The function `?lansf` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real symmetric matrix A in the [rectangular full packed \(RFP\) format](#).

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Specifies the value to be returned by the routine:</p> <p>= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A.</p> <p>= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),</p> <p>= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).</p>
<i>transr</i>	<p>CHARACTER*1.</p> <p>Specifies whether the RFP format of matrix A is normal or transposed format.</p> <p>If <i>transr</i> = 'N': RFP format is normal;</p> <p>if <i>transr</i> = 'T': RFP format is transposed.</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether the RFP matrix A came from upper or lower triangular matrix.</p> <p>If <i>uplo</i> = 'U': RFP matrix A came from an upper triangular matrix;</p> <p>if <i>uplo</i> = 'L': RFP matrix A came from a lower triangular matrix.</p>
<i>n</i>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p> <p>When $n = 0$, <code>?lansf</code> is set to zero.</p>
<i>a</i>	<p>REAL for <code>slansf</code></p> <p>DOUBLE PRECISION for <code>dlansf</code></p> <p>Array, DIMENSION $(n*(n+1)/2)$.</p> <p>The upper (if <i>uplo</i> = 'U') or lower (if <i>uplo</i> = 'L') part of the symmetric matrix A stored in RFP format.</p>
<i>work</i>	<p>REAL for <code>slansf</code>.</p> <p>DOUBLE PRECISION for <code>dlansf</code>.</p> <p>Workspace array, DIMENSION $(\max(1, lwork))$, where</p> <p>$lwork \geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.</p>

Output Parameters

<i>val</i>	<p>REAL for <code>slansf</code></p> <p>DOUBLE PRECISION for <code>dlansf</code></p>
------------	---

Value returned by the function.

?lanhf

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian matrix in RFP format.

Syntax

```
val = clanhf(norm, transr, uplo, n, a, work)
```

```
val = zlanhf(norm, transr, uplo, n, a, work)
```

Include Files

- mkl.fi

Description

The function ?lanhf returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n complex Hermitian matrix A in the [rectangular full packed \(RFP\) format](#).

Input Parameters

<code>norm</code>	<p>CHARACTER*1.</p> <p>Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<code>transr</code>	<p>CHARACTER*1.</p> <p>Specifies whether the RFP format of matrix A is normal or conjugate-transposed format.</p> <p>If <code>transr</code> = 'N': RFP format is normal;</p> <p>if <code>transr</code> = 'C': RFP format is conjugate-transposed.</p>
<code>uplo</code>	<p>CHARACTER*1.</p> <p>Specifies whether the RFP matrix A came from upper or lower triangular matrix.</p> <p>If <code>uplo</code> = 'U': RFP matrix A came from an upper triangular matrix;</p> <p>if <code>uplo</code> = 'L': RFP matrix A came from a lower triangular matrix.</p>
<code>n</code>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p> <p>When $n = 0$, ?lanhf is set to zero.</p>

a COMPLEX for `clanhf`
 DOUBLE COMPLEX for `zlanhf`
 Array, DIMENSION $(n*(n+1)/2)$.
 The upper (if *uplo* = 'U') or lower (if *uplo* = 'L') part of the Hermitian matrix *A* stored in [RFP format](#).

work COMPLEX for `clanhf`.
 DOUBLE COMPLEX for `zlanhf`.
 Workspace array, DIMENSION $(\max(1, lwork))$, where
 $lwork \geq n$ when *norm* = 'I' or '1' or 'O'; otherwise, *work* is not referenced.

Output Parameters

val COMPLEX for `clanhf`
 DOUBLE COMPLEX for `zlanhf`
 Value returned by the function.

?tfttp

Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).

Syntax

```
call stfttp( transr, uplo, n, arf, ap, info )
call dtfttp( transr, uplo, n, arf, ap, info )
call ctfttp( transr, uplo, n, arf, ap, info )
call ztfttp( transr, uplo, n, arf, ap, info )
```

Include Files

- `mkl.fi`

Description

The routine copies a triangular matrix *A* from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

transr CHARACTER*1.
 = 'N': *arf* is in the Normal format,
 = 'T': *arf* is in the Transpose format (for `stfttp` and `dtfttp`),
 = 'C': *arf* is in the Conjugate-transpose format (for `ctfttp` and `ztfttp`).

uplo CHARACTER*1.

Specifies whether A is upper or lower triangular:

= 'U': A is upper triangular,

= 'L': A is lower triangular.

n INTEGER. The order of the matrix A . $n \geq 0$.

arf REAL for stfttp,
DOUBLE PRECISION for dtfttp,
COMPLEX for ctfttp,
DOUBLE COMPLEX for ztfttp.
Array, size at least $\max(1, n*(n+1)/2)$.
On entry, the upper or lower triangular matrix A stored in the RFP format.

Output Parameters

ap REAL for stfttp,
DOUBLE PRECISION for dtfttp,
COMPLEX for ctfttp,
DOUBLE COMPLEX for ztfttp.
Array, size at least $\max(1, n*(n+1)/2)$.
On exit, the upper or lower triangular matrix A , packed columnwise in a linear array.
The j -th column of A is stored in the array ap as follows:
if $uplo = 'U'$, $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,
if $uplo = 'L'$, $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
 $info$ INTEGER. If $info = 0$, the execution is successful.
If $info < 0$, the i -th parameter had an illegal value.
If $info = -1011$, memory allocation error occurred.

?tfttr

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR) .

Syntax

```
call stfttr( transr, uplo, n, arf, a, lda, info )
call dtfttr( transr, uplo, n, arf, a, lda, info )
call ctfttr( transr, uplo, n, arf, a, lda, info )
call ztfttr( transr, uplo, n, arf, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine copies a triangular matrix A from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>transr</i>	CHARACTER*1. = 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for <i>stfttr</i> and <i>dtfttr</i>), = 'C': <i>arf</i> is in the Conjugate-transpose format (for <i>ctfttr</i> and <i>ztfttr</i>).
<i>uplo</i>	CHARACTER*1. Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular.
<i>n</i>	INTEGER. The order of the matrices <i>arf</i> and a . $n \geq 0$.
<i>arf</i>	REAL for <i>stfttr</i> , DOUBLE PRECISION for <i>dtfttr</i> , COMPLEX for <i>ctfttr</i> , DOUBLE COMPLEX for <i>ztfttr</i> . Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix A stored in the RFP format.
<i>lda</i>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	REAL for <i>stfttr</i> , DOUBLE PRECISION for <i>dtfttr</i> , COMPLEX for <i>ctfttr</i> , DOUBLE COMPLEX for <i>ztfttr</i> . Array, size (<i>lda</i> , *). On exit, the triangular matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the i -th parameter had an illegal value. If <i>info</i> = -1011, memory allocation error occurred.

?tpqrt2

Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q .

Syntax

```
call stpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call dtpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call ctpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call ztpqrt2(m, n, l, a, lda, b, ldb, t, ldt, info)
call tpqrt2(a, b, t [, info])
```

Include Files

- mkl.fi, lapack.f90

Description

The input matrix C is an $(n+m)$ -by- n matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \begin{matrix} \leftarrow n \times n \text{ upper triangular} \\ \leftarrow m \times n \text{ pentagonal} \end{matrix}$$

where A is an n -by- n upper triangular matrix, and B is an m -by- n pentagonal matrix consisting of an $(m-1)$ -by- n rectangular matrix $B1$ on top of an 1 -by- n upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \begin{matrix} \leftarrow (m-1) \times n \text{ rectangular} \\ \leftarrow 1 \times n \text{ upper trapezoidal} \end{matrix}$$

The upper trapezoidal matrix $B2$ consists of the first l rows of an n -by- n upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If $l=0$, B is an m -by- n rectangular matrix. If $m=l=n$, B is upper triangular. The matrix W contains the elementary reflectors $H(i)$ in the i th column below the diagonal (of A) in the $(n+m)$ -by- n input matrix C so that W can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \begin{matrix} \leftarrow n \times n \text{ identity} \\ \leftarrow m \times n \text{ pentagonal} \end{matrix}$$

Thus, V contains all of the information needed for W , and is returned in array b .

NOTE

V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \leftarrow \begin{matrix} (m-l) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{matrix}$$

The columns of V represent the vectors which define the $H(i)$ s.

The $(m+n)$ -by- $(m+n)$ block reflector H is then given by

$H = I - W^* T^* W^T$ for real flavors, and

$H = I - W^* T^* W^H$ for complex flavors

where W^T is the transpose of W , W^H is the conjugate transpose of W , and T is the upper triangular factor of the block reflector.

Input Parameters

m	INTEGER. The total number of rows in the matrix B ($m \geq 0$).
n	INTEGER. The number of columns in B and the order of the triangular matrix A ($n \geq 0$).
l	INTEGER. The number of rows of the upper trapezoidal part of B ($\min(m, n) \geq l \geq 0$).
a, b	REAL for <code>stpqrt2</code> DOUBLE PRECISION for <code>dtpqrt2</code> COMPLEX for <code>ctpqrt2</code> COMPLEX*16 for <code>ztpqrt2</code> . Arrays: a , size (lda, n) contains the n -by- n upper triangular matrix A . b , size (ldb, n) , the pentagonal m -by- n matrix B . The first $(m-l)$ rows contain the rectangular $B1$ matrix, and the next l rows contain the upper trapezoidal $B2$ matrix.
lda	INTEGER. The leading dimension of a ; at least $\max(1, n)$.
ldb	INTEGER. The leading dimension of b ; at least $\max(1, m)$.
ldt	INTEGER. The leading dimension of t ; at least $\max(1, n)$.

Output Parameters

a	The elements on and above the diagonal of the array contain the upper triangular matrix R .
b	The pentagonal matrix V .
t	REAL for <code>stpqrt2</code> DOUBLE PRECISION for <code>dtpqrt2</code> COMPLEX for <code>ctpqrt2</code>

COMPLEX*16 for ztpqrt2.

Array, size (ldt , n).

The upper n -by- n upper triangular factor T of the block reflector.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tprfb

Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.

Syntax

```
call stprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)
```

```
call dtprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)
```

```
call ctprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)
```

```
call ztprfb(side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, a, lda, b, ldb,
work, ldwork)
```

```
call tprfb(t, v, a, b[, direct][, storev][, side][, trans])
```

Include Files

- mkl.fi, lapack.f90

Description

The ?tprfb routine applies a real or complex "triangular-pentagonal" block reflector H , H^T , or H^H from either the left or the right to a real or complex matrix C , which is composed of two blocks A and B .

The block B is m -by- n . If *side* = 'R', A is m -by- k , and if *side* = 'L', A is of size k -by- n .

$$\begin{array}{ll}
 \text{direct} = \text{'F'} & \text{direct} = \text{'B'} \\
 \text{side} = \text{'R'} & C = \begin{bmatrix} A & B \end{bmatrix} \quad C = \begin{bmatrix} B & A \end{bmatrix} \\
 \text{side} = \text{'L'} & C = \begin{bmatrix} A \\ B \end{bmatrix} \quad C = \begin{bmatrix} B \\ A \end{bmatrix}
 \end{array}$$

The pentagonal matrix V is composed of a rectangular block $V1$ and a trapezoidal block $V2$. The size of the trapezoidal block is determined by the parameter l , where $0 \leq l \leq k$. if $l=k$, the $V2$ block of V is triangular; if $l=0$, there is no trapezoidal block, thus $V = V1$ is rectangular.

<i>direct</i> ='F'	<i>direct</i> ='B'
<i>storev</i> ='C'	
$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 \\ V1 \end{bmatrix}$
V2 is upper trapezoidal (first <i>l</i> rows of <i>k</i> -by- <i>k</i> upper triangular)	V2 is lower trapezoidal (last <i>l</i> rows of <i>k</i> -by- <i>k</i> lower triangular matrix)
<i>storev</i> ='R'	
$V = \begin{bmatrix} V1 & V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 & V1 \end{bmatrix}$
V2 is lower trapezoidal (first <i>l</i> columns of <i>k</i> -by- <i>k</i> lower triangular matrix)	V2 is upper trapezoidal (last <i>l</i> columns of <i>k</i> -by- <i>k</i> upper triangular matrix)

<i>storev</i> ='C'	<i>side</i> ='L'	<i>side</i> ='R'
	<i>V</i> is <i>m</i> -by- <i>k</i>	<i>V</i> is <i>n</i> -by- <i>k</i>
	<i>V2</i> is <i>l</i> -by- <i>k</i>	<i>V2</i> is <i>l</i> -by- <i>k</i>
<i>storev</i> ='R'	<i>V</i> is <i>k</i> -by- <i>m</i>	<i>V</i> is <i>k</i> -by- <i>n</i>
	<i>V2</i> is <i>k</i> -by- <i>l</i>	<i>V2</i> is <i>k</i> -by- <i>l</i>

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply H , H^T , or H^H from the left, = 'R': apply H , H^T , or H^H from the right.
<i>trans</i>	CHARACTER*1. = 'N': apply H (no transpose), = 'T': apply H^T (transpose), = 'C': apply H^H (conjugate transpose).
<i>direct</i>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors: = 'F': $H = H(1) H(2) \dots H(k)$ (Forward), = 'B': $H = H(k) \dots H(2) H(1)$ (Backward).
<i>storev</i>	CHARACTER*1. Indicates how the vectors that define the elementary reflectors are stored: = 'C': Columns, = 'R': Rows.
<i>m</i>	INTEGER. The total number of rows in the matrix B ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in B ($n \geq 0$).

<i>k</i>	<p>INTEGER. The order of the matrix <i>T</i>, which is the number of elementary reflectors whose product defines the block reflector. ($k \geq 0$)</p>
<i>l</i>	<p>INTEGER. The order of the trapezoidal part of <i>V</i>. ($k \geq l \geq 0$).</p>
<i>v</i>	<p>REAL for stprfb DOUBLE PRECISION for dtpfrfb COMPLEX for ctpfrfb COMPLEX*16 for ztpfrfb. DIMENSION (<i>ldv</i>, <i>k</i>) if <i>storev</i> = 'C', DIMENSION (<i>ldv</i>, <i>m</i>) if <i>storev</i> = 'R' and <i>side</i> = 'L', DIMENSION (<i>ldv</i>, <i>n</i>) if <i>storev</i> = 'R' and <i>side</i> = 'R'. The pentagonal matrix <i>V</i>, which contains the elementary reflectors <i>H</i>(1), <i>H</i>(2), ..., <i>H</i>(<i>k</i>).</p>
<i>ldv</i>	<p>INTEGER. The leading dimension of the array <i>v</i>. If <i>storev</i> = 'C' and <i>side</i> = 'L', at least $\max(1, m)$. If <i>storev</i> = 'C' and <i>side</i> = 'R', at least $\max(1, n)$. If <i>storev</i> = 'R' , at least <i>k</i>.</p>
<i>t</i>	<p>REAL for stprfb DOUBLE PRECISION for dtpfrfb COMPLEX for ctpfrfb COMPLEX*16 for ztpfrfb. Array size (<i>ldt</i>, <i>k</i>). The triangular <i>k</i>-by-<i>k</i> matrix <i>T</i> in the representation of the block reflector.</p>
<i>ldt</i>	<p>INTEGER. The leading dimension of the array <i>t</i> ($ldt \geq k$).</p>
<i>a</i>	<p>REAL for stprfb DOUBLE PRECISION for dtpfrfb COMPLEX for ctpfrfb COMPLEX*16 for ztpfrfb. DIMENSION (<i>lda</i>, <i>n</i>) if <i>side</i> = 'L', DIMENSION (<i>lda</i>, <i>k</i>) if <i>side</i> = 'R'. The <i>k</i>-by-<i>n</i> or <i>m</i>-by-<i>k</i> matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array <i>a</i>. If <i>side</i> = 'L', at least $\max(1, k)$. If <i>side</i> = 'R', at least $\max(1, m)$.</p>
<i>b</i>	<p>REAL for stprfb DOUBLE PRECISION for dtpfrfb</p>

	COMPLEX for ctpprfb
	COMPLEX*16 for ztpprfb.
	Array size (ldb, n), the m -by- n matrix B .
<i>ldb</i>	INTEGER. The leading dimension of the array b ($ldb \geq \max(1, m)$).
<i>work</i>	REAL for stpprfb
	DOUBLE PRECISION for dtpprfb
	COMPLEX for ctpprfb
	COMPLEX*16 for ztpprfb.
	DIMENSION ($ldwork, n$) if $side = 'L'$,
	DIMENSION ($ldwork, k$) if $side = 'R'$.
	Workspace array.
<i>ldwork</i>	INTEGER. The leading dimension of the array <i>work</i> .
	If $side = 'L'$, at least k .
	If $side = 'R'$, at least m .

Output Parameters

<i>a</i>	Contains the corresponding block of H^*C , H^T*C , H^H*C , C^*H , C^*H^T , or C^*H^H .
<i>b</i>	Contains the corresponding block of H^*C , H^T*C , H^H*C , C^*H , C^*H^T , or C^*H^H .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info < 0$, the i -th parameter had an illegal value. If $info = -1011$, memory allocation error occurred.

?tpptf

Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

Syntax

```
call stpptf( transr, uplo, n, ap, arf, info )
call dtpptf( transr, uplo, n, ap, arf, info )
call ctpptf( transr, uplo, n, ap, arf, info )
call ztpptf( transr, uplo, n, ap, arf, info )
```

Include Files

- mkl.fi

Description

The routine copies a triangular matrix A from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>transr</i>	<p>CHARACTER*1.</p> <p>= 'N': <i>arf</i> must be in the Normal format,</p> <p>= 'T': <i>arf</i> must be in the Transpose format (for <i>stpttf</i> and <i>dtpttf</i>),</p> <p>= 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctpttf</i> and <i>ztpttf</i>).</p>
<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether <i>A</i> is upper or lower triangular:</p> <p>= 'U': <i>A</i> is upper triangular,</p> <p>= 'L': <i>A</i> is lower triangular.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.</p>
<i>ap</i>	<p>REAL for <i>stpttf</i>,</p> <p>DOUBLE PRECISION for <i>dtpttf</i>,</p> <p>COMPLEX for <i>ctpttf</i>,</p> <p>DOUBLE COMPLEX for <i>ztpttf</i>.</p> <p>Array, size at least $\max(1, n*(n+1)/2)$.</p> <p>On entry, the upper or lower triangular matrix <i>A</i>, packed columnwise in a linear array.</p> <p>The <i>j</i>-th column of <i>A</i> is stored in the array <i>ap</i> as follows:</p> <p>if <i>uplo</i> = 'U', $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,</p> <p>if <i>uplo</i> = 'L', $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.</p>

Output Parameters

<i>arf</i>	<p>REAL for <i>stpttf</i>,</p> <p>DOUBLE PRECISION for <i>dtpttf</i>,</p> <p>COMPLEX for <i>ctpttf</i>,</p> <p>DOUBLE COMPLEX for <i>ztpttf</i>.</p> <p>Array, size at least $\max(1, n*(n+1)/2)$.</p> <p>On exit, the upper or lower triangular matrix <i>A</i> stored in the RFP format.</p>
<i>info</i>	<p>INTEGER.</p> <p>=0: successful exit,</p> <p>< 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If <i>info</i> = -1011, memory allocation error occurred.</p>

?tptr

Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR) .

Syntax

```
call stpttr( uplo, n, ap, a, lda, info )
call dtpttr( uplo, n, ap, a, lda, info )
call ctpttr( uplo, n, ap, a, lda, info )
call ztpttr( uplo, n, ap, a, lda, info )
```

Include Files

- mkl.fi

Description

The routine copies a triangular matrix A from the standard packed format to the standard full format.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1.</p> <p>Specifies whether A is upper or lower triangular:</p> <p>= 'U': A is upper triangular,</p> <p>= 'L': A is lower triangular.</p>
<i>n</i>	<p>INTEGER. The order of the matrices ap and a. $n \geq 0$.</p>
<i>ap</i>	<p>REAL for stpttr,</p> <p>DOUBLE PRECISION for dtpttr,</p> <p>COMPLEX for ctpttr,</p> <p>DOUBLE COMPLEX for ztpttr.</p> <p>On entry, the upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array ap as follows:</p> <p>if $uplo = 'U'$, $ap(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$,</p> <p>if $uplo = 'L'$, $ap(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of the array a. $lda \geq \max(1,n)$.</p>

Output Parameters

<i>a</i>	<p>REAL for stpttr,</p> <p>DOUBLE PRECISION for dtpttr,</p> <p>COMPLEX for ctpttr,</p> <p>DOUBLE COMPLEX for ztpttr.</p> <p>Array, size (lda, *).</p>
----------	--

On exit, the triangular matrix *A*. If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = -1011, memory allocation error occurred.

?trttf

Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).

Syntax

```
call strttf( transr, uplo, n, a, lda, arf, info )
call dtrttf( transr, uplo, n, a, lda, arf, info )
call ctrttf( transr, uplo, n, a, lda, arf, info )
call ztrttf( transr, uplo, n, a, lda, arf, info )
```

Include Files

- mkl.fi

Description

The routine copies a triangular matrix *A* from the standard full format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

transr CHARACTER*1.
 = 'N': *arf* must be in the Normal format,
 = 'T': *arf* must be in the Transpose format (for *strttf* and *dtrttf*),
 = 'C': *arf* must be in the Conjugate-transpose format (for *ctrttf* and *ztrttf*).

uplo CHARACTER*1.
 Specifies whether *A* is upper or lower triangular:
 = 'U': *A* is upper triangular,
 = 'L': *A* is lower triangular.

n INTEGER. The order of the matrix *A*. $n \geq 0$.

a REAL for *strttf*,

DOUBLE PRECISION for dtrttf,
 COMPLEX for ctrttf,
 DOUBLE COMPLEX for ztrttf.

Array, size (lda, n) .

On entry, the triangular matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

arf REAL for strttf,
 DOUBLE PRECISION for dtrttf,
 COMPLEX for ctrttf,
 DOUBLE COMPLEX for ztrttf.
 Array, size at least $\max(1, n*(n+1)/2)$.

On exit, the upper or lower triangular matrix A stored in the RFP format.

info INTEGER. If $info = 0$, the execution is successful.
 If $info < 0$, the i -th parameter had an illegal value.
 If $info = -1011$, memory allocation error occurred.

?trttp

Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP) .

Syntax

```
call strttp( uplo, n, a, lda, ap, info )
call dtrttp( uplo, n, a, lda, ap, info )
call ctrttp( uplo, n, a, lda, ap, info )
call ztrttp( uplo, n, a, lda, ap, info )
```

Include Files

- mkl.fi

Description

The routine copies a triangular matrix A from the standard full format to the standard packed format.

Input Parameters

uplo CHARACTER*1.

Specifies whether A is upper or lower triangular:

= 'U': A is upper triangular,

= 'L': A is lower triangular.

n INTEGER. The order of the matrix A , $n \geq 0$.

a REAL for strttp,
DOUBLE PRECISION for dtrttp,
COMPLEX for ctrttp,
DOUBLE COMPLEX for ztrttp.
Array, size (lda, n) .
On entry, the triangular matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

ap REAL for strttp,
DOUBLE PRECISION for dtrttp,
COMPLEX for ctrttp,
DOUBLE COMPLEX for ztrttp.
Array, size at least $\max(1, n*(n+1)/2)$.
On exit, the upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:
if $uplo = 'U'$, $ap(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$,
if $uplo = 'L'$, $ap(i + (j-1)*(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

$info$ INTEGER. If $info = 0$, the execution is successful.
If $info < 0$, the i -th parameter had an illegal value.
If $info = -1011$, memory allocation error occurred.

?pstf2

Computes the Cholesky factorization with complete pivoting of a real symmetric or complex Hermitian positive semi-definite matrix.

Syntax

```
call spstf2( uplo, n, a, lda, piv, rank, tol, work, info )
call dpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
call cpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
```

```
call zpstf2( uplo, n, a, lda, piv, rank, tol, work, info )
```

Include Files

- mkl.fi

Description

The real flavors `spstf2` and `dpstf2` compute the Cholesky factorization with complete pivoting of a real symmetric positive semi-definite matrix A . The complex flavors `cpstf2` and `zpstf2` compute the Cholesky factorization with complete pivoting of a complex Hermitian positive semi-definite matrix A . The factorization has the form:

$P^T * A * P = U^T * U$, if `uplo` = 'U' for real flavors,

$P^T * A * P = U^H * U$, if `uplo` = 'U' for complex flavors,

$P^T * A * P = L * L^T$, if `uplo` = 'L' for real flavors,

$P^T * A * P = L * L^H$, if `uplo` = 'L' for complex flavors,

where U is an upper triangular matrix and L is lower triangular, and P is stored as vector `piv`.

This algorithm does not check that A is positive semi-definite. This version of the algorithm calls [level 2 BLAS](#).

Input Parameters

<code>uplo</code>	<p>CHARACTER*1.</p> <p>Specifies whether the upper or lower triangular part of the symmetric or Hermitian matrix A is stored:</p> <p>= 'U': Upper triangular,</p> <p>= 'L': Lower triangular.</p>
<code>n</code>	<p>INTEGER. The order of the matrix A. $n \geq 0$.</p>
<code>a</code>	<p>REAL for <code>spstf2</code>,</p> <p>DOUBLE PRECISION for <code>dpstf2</code>,</p> <p>COMPLEX for <code>cpstf2</code>,</p> <p>DOUBLE COMPLEX for <code>zpstf2</code>.</p> <p>Array, DIMENSION (<code>lda</code>, *).</p> <p>On entry, the symmetric matrix A. If <code>uplo</code> = 'U', the leading n-by-n upper triangular part of the array <code>a</code> contains the upper triangular part of the matrix A, and the strictly lower triangular part of <code>a</code> is not referenced. If <code>uplo</code> = 'L', the leading n-by-n lower triangular part of the array <code>a</code> contains the lower triangular part of the matrix A, and the strictly upper triangular part of <code>a</code> is not referenced.</p>
<code>tol</code>	<p>REAL for <code>spstf2</code> and <code>cpstf2</code>,</p> <p>DOUBLE PRECISION for <code>dpstf2</code> and <code>zpstf2</code>.</p> <p>A user-defined tolerance.</p> <p>If <code>tol</code> < 0, $n * ulp * \max(A(k,k))$ will be used (<code>ulp</code> is the Unit in the Last Place, or Unit of Least Precision). The algorithm terminates at the $(k - 1)$-st step if the pivot is not greater than <code>tol</code>.</p>

lda INTEGER. The leading dimension of the matrix *A*. $lda \geq \max(1, n)$.

work REAL for `spstf2` and `cpstf2`,
 DOUBLE PRECISION for `dpstf2` and `zpstf2`.
 Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

piv INTEGER. Array. DIMENSION at least $\max(1, n)$.
piv is such that the non-zero entries are $P(piv(k), k) = 1$.

a On exit, if *info* = 0, the factor U or L from the Cholesky factorization stored the same way as the matrix *A* is stored on entry.

rank INTEGER.
 The rank of *A*, determined by the number of steps the algorithm completed.

info INTEGER.
 < 0: if *info* = -*k*, the *k*-th parameter had an illegal value,
 =0: the algorithm completed successfully,
 > 0: the matrix *A* is rank-deficient with the computed rank, returned in *rank*, or indefinite.

dlat2s

Converts a double-precision triangular matrix to a single-precision triangular matrix.

Syntax

call dlat2s(*uplo*, *n*, *a*, *lda*, *sa*, *ldsa*, *info*)

Include Files

- `mkl.fi`

Description

This routine converts a double-precision triangular matrix *A* to a single-precision triangular matrix *SA*. `dlat2s` checks that all the elements of *A* are between *-RMAX* and *RMAX*, where *RMAX* is the overflow for the single-precision arithmetic. If this condition is not met, the conversion is aborted and a flag is raised. The routine does no parameter checking.

Input Parameters

uplo CHARACTER*1.
 Specifies whether the matrix *A* is upper or lower triangular:
 = 'U': *A* is upper triangular,
 = 'L': *A* is lower triangular.

n INTEGER. The number of rows and columns of the matrix *A*. $n \geq 0$.

a DOUBLE PRECISION.
 Array, DIMENSION (*lda*, *).
 On entry, the *n*-by-*n* triangular matrix *A*.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

ldsa INTEGER. The leading dimension of the array *sa*. $ldsa \geq \max(1, n)$.

Output Parameters

sa REAL.
 Array, DIMENSION (*ldsa*, *).
 Only the part of *sa* determined by *uplo* is referenced. On exit,

- if *info* = 0, the *n*-by-*n* triangular matrix *SA*,
- if *info* > 0, the content of the part of *sa* determined by *uplo* is unspecified.

info INTEGER.
 =0: successful exit,
 > 0: an element of the matrix *A* is greater than the single-precision overflow threshold; in this case, the content of the part of *sa* determined by *uplo* is unspecified on exit.

zlat2c

Converts a double complex triangular matrix to a complex triangular matrix.

Syntax

call zlat2c(*uplo*, *n*, *a*, *lda*, *sa*, *ldsa*, *info*)

Include Files

- mkl.fi

Description

This routine is declared in `mkl_lapack.fi`.

The routine converts a DOUBLE COMPLEX triangular matrix *A* to a COMPLEX triangular matrix *SA*. `zlat2c` checks that the real and complex parts of all the elements of *A* are between *-RMAX* and *RMAX*, where *RMAX* is the overflow for the single-precision arithmetic. If this condition is not met, the conversion is aborted and a flag is raised. The routine does no parameter checking.

Input Parameters

uplo CHARACTER*1.
 Specifies whether the matrix *A* is upper or lower triangular:
 = 'U': *A* is upper triangular,
 = 'L': *A* is lower triangular.

<i>n</i>	INTEGER. The number of rows and columns in the matrix <i>A</i> . $n \geq 0$.
<i>a</i>	DOUBLE COMPLEX. Array, DIMENSION (<i>lda</i> , *). On entry, the <i>n</i> -by- <i>n</i> triangular matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> . $ldsa \geq \max(1, n)$.

Output Parameters

<i>sa</i>	COMPLEX. Array, DIMENSION (<i>ldsa</i> , *). Only the part of <i>sa</i> determined by <i>uplo</i> is referenced. On exit, <ul style="list-style-type: none"> if <i>info</i> = 0, the <i>n</i>-by-<i>n</i> triangular matrix <i>sa</i>, if <i>info</i> > 0, the content of the part of <i>sa</i> determined by <i>uplo</i> is unspecified.
<i>info</i>	INTEGER. =0: successful exit, > 0: the real or complex part of an element of the matrix <i>A</i> is greater than the single-precision overflow threshold; in this case, the content of the part of <i>sa</i> determined by <i>uplo</i> is unspecified on exit.

?lapc2

Copies all or part of a real two-dimensional array to a complex array.

Syntax

```
call clacp2( uplo, m, n, a, lda, b, ldb )
call zlapc2( uplo, m, n, a, lda, b, ldb )
```

Include Files

- mkl.fi

Description

The routine copies all or part of a real matrix *A* to another matrix *B*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix <i>A</i> to be copied to <i>B</i> . If <i>uplo</i> = 'U', the upper triangular part of <i>A</i> ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i> .
-------------	--

Otherwise, all of the matrix A is copied.

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a REAL for `clacp2`

DOUBLE PRECISION for `zlacp2`

Array, size at least (lda, n) , contains the m -by- n matrix A .

If `uplo` = 'U', only the upper triangle or trapezoid is accessed; if `uplo` = 'L', only the lower triangle or trapezoid is accessed.

lda INTEGER. The leading dimension of a ; $lda \geq \max(1, m)$.

ldb INTEGER. The leading dimension of the output array b ; $ldb \geq \max(1, m)$.

Output Parameters

b COMPLEX for `clacp2`

DOUBLE COMPLEX for `zlacp2`.

Array, size (ldb, n) .

On exit, $B = A$ in the locations specified by `uplo`.

$info$ INTEGER. If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?la_gbamv

Performs a matrix-vector operation to calculate error bounds.

Syntax

`call sla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)`

`call dla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)`

`call cla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)`

`call zla_gbamv(trans, m, n, kl, ku, alpha, ab, ldab, x, incx, beta, y, incy)`

Include Files

- `mkl.fi`

Description

The `?la_gbamv` function performs one of the matrix-vector operations defined as

$y := \alpha \cdot \text{abs}(A) \cdot \text{abs}(x) + \beta \cdot \text{abs}(y),$

or

$y := \alpha \cdot \text{abs}(A)^T \cdot \text{abs}(x) + \beta \cdot \text{abs}(y),$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- n matrix, with kl sub-diagonals and ku super-diagonals.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

$trans$	<p>INTEGER. Specifies the operation to be performed:</p> <p>If $trans = 'BLAS_NO_TRANS'$, then $y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y)$</p> <p>If $trans = 'BLAS_TRANS'$, then $y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y)$</p> <p>If $trans = 'BLAS_CONJ_TRANS'$, then $y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y)$</p> <p>The parameter is unchanged on exit.</p>
m	<p>INTEGER. Specifies the number of rows of the matrix A.</p> <p>The value of m must be at least zero. Unchanged on exit.</p>
n	<p>INTEGER. Specifies the number of columns of the matrix A.</p> <p>The value of n must be at least zero. Unchanged on exit.</p>
kl	<p>INTEGER. Specifies the number of sub-diagonals within the band of A.</p> <p>$kl \geq 0$.</p>
ku	<p>INTEGER. Specifies the number of super-diagonals within the band of A.</p> <p>$ku \geq 0$.</p>
α	<p>REAL for <code>sla_gbamv</code> and <code>cla_gbamv</code></p> <p>DOUBLE PRECISION for <code>dla_gbamv</code> and <code>zla_gbamv</code></p> <p>Specifies the scalar α. Unchanges on exit.</p>
ab	<p>REAL for <code>sla_gbamv</code></p> <p>DOUBLE PRECISION for <code>dla_gbamv</code></p> <p>COMPLEX for <code>cla_gbamv</code></p> <p>DOUBLE COMPLEX for <code>zla_gbamv</code></p> <p>Array, DIMENSION($ldab$, *).</p> <p>Before entry, the leading m-by-n part of the array ab must contain the matrix of coefficients. The second dimension of ab must be at least $\max(1, n)$. Unchanged on exit.</p>

<i>ldab</i>	INTEGER. Specifies the leading dimension of <i>ab</i> as declared in the calling (sub)program. The value of <i>ldab</i> must be at least $\max(1, m)$. Unchanged on exit.
<i>x</i>	REAL for <i>sla_gbamv</i> DOUBLE PRECISION for <i>dla_gbamv</i> COMPLEX for <i>cla_gbamv</i> DOUBLE COMPLEX for <i>zla_gbamv</i> Array, DIMENSION $(1 + (n - 1) * \text{abs}(\text{incx}))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(\text{incx}))$ otherwise. Before entry, the incremented array <i>x</i> must contain the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>beta</i>	REAL for <i>sla_gbamv</i> and <i>cla_gbamv</i> DOUBLE PRECISION for <i>dla_gbamv</i> and <i>zla_gbamv</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is zero, you do not need to set <i>y</i> on input.
<i>y</i>	REAL for <i>sla_gbamv</i> and <i>cla_gbamv</i> DOUBLE PRECISION for <i>dla_gbamv</i> and <i>zla_gbamv</i> Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incy}))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with <i>beta</i> non-zero, the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. Unchanged on exit.

Output Parameters

<i>y</i>	Updated vector <i>y</i> .
----------	---------------------------

?la_gbrcond

Estimates the Skeel condition number for a general banded matrix.

Syntax

call *sla_gbrcond*(*trans*, *n*, *kl*, *ku*, *ab*, *ldab*, *afb*, *ldafb*, *ipiv*, *cmode*, *c*, *info*, *work*, *iwork*)

call `dla_gbrcond(trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, cmode, c, info, work, iwork)`

Include Files

- `mkl.fi`

Description

The function estimates the Skeel condition number of

$\text{op}(A) * \text{op2}(C)$

where

the `cmode` parameter determines `op2` as follows:

<code>cmode</code> Value	<code>op2(C)</code>
1	C
0	I
-1	$\text{inv}(C)$

The Skeel condition number

$\text{cond}(A) = \text{norminf}(|\text{inv}(A)| |A|)$

is computed by computing scaling factors R such that

$\text{diag}(R) * A * \text{op2}(C)$

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<code>trans</code>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <code>trans</code> = 'N', the system has the form $A * X = B$.</p> <p>If <code>trans</code> = 'T', the system has the form $A^T * X = B$.</p> <p>If <code>trans</code> = 'C', the system has the form $A^H * X = B$.</p>
<code>n</code>	<p>INTEGER. The number of linear equations, that is, the order of the matrix A; $n \geq 0$.</p>
<code>kl</code>	<p>INTEGER. The number of subdiagonals within the band of A; $kl \geq 0$.</p>
<code>ku</code>	<p>INTEGER. The number of superdiagonals within the band of A; $ku \geq 0$.</p>
<code>ab, afb, c, work</code>	<p>REAL for <code>sla_gbrcond</code></p> <p>DOUBLE PRECISION for <code>dla_gbrcond</code></p> <p>Arrays:</p> <p><code>ab(ldab,*)</code> contains the original band matrix A stored in rows from 1 to $kl + ku + 1$. The j-th column of A is stored in the j-th column of the array <code>ab</code> as follows:</p> <p>$\text{ab}(ku+1+i-j, j) = A(i, j)$</p> <p>for</p>

$\max(1, j - ku) \leq i \leq \min(n, j + kl)$

afb(ldafb,)* contains details of the LU factorization of the band matrix *A*, as returned by *?gbtrf*. *U* is stored as an upper triangular band matrix with *kl+ku* superdiagonals in rows 1 to *kl+ku+1*, and the multipliers used during the factorization are stored in rows *kl+ku+2* to *2*kl+ku+1*.

c, *DIMENSION**n*. The vector *C* in the formula $\text{op}(A) * \text{op2}(C)$.

work is a workspace array of *DIMENSION* $(5*n)$.

The second dimension of *ab* and *afb* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*. $ldab \geq kl + ku + 1$.

ldaafb INTEGER. The leading dimension of *afb*. $ldaafb \geq 2*kl + ku + 1$.

ipiv INTEGER.

Array with *DIMENSION**n*. The pivot indices from the factorization $A = P*L*U$ as computed by *?gbtrf*. Row *i* of the matrix was interchanged with row *ipiv(i)*.

cmode INTEGER. Determines $\text{op2}(C)$ in the formula $\text{op}(A) * \text{op2}(C)$ as follows:

If *cmode* = 1, $\text{op2}(C) = C$.

If *cmode* = 0, $\text{op2}(C) = I$.

If *cmode* = -1, $\text{op2}(C) = \text{inv}(C)$.

iwork INTEGER. Workspace array with *DIMENSION**n*.

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If *i* > 0, the *i*-th parameter is invalid.

See Also

[?gbtrf](#)

?la_gbrcond_c

*Computes the infinity norm condition number of $\text{op}(A) * \text{inv}(\text{diag}(C))$ for general banded matrices.*

Syntax

```
call cla_gbrcond_c( trans, n, kl, ku, ab, ldab, afb, ldaafb, ipiv, c, capply, info,
work, rwork )
```

```
call zla_gbrcond_c( trans, n, kl, ku, ab, ldab, afb, ldaafb, ipiv, c, capply, info,
work, rwork )
```

Include Files

- `mkl.fi`

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{inv}(\text{diag}(c))$

where the c is a REAL vector for `cla_gbrcond_c` and a DOUBLE PRECISION vector for `zla_gbrcond_c`.

Input Parameters

<i>trans</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A*X = B$ (No transpose)</p> <p>If <i>trans</i> = 'T', the system has the form $A^T*X = B$ (Transpose)</p> <p>If <i>trans</i> = 'C', the system has the form $A^H*X = B$ (Conjugate Transpose = Transpose)</p>
<i>n</i>	<p>INTEGER. The number of linear equations, that is, the order of the matrix A; $n \geq 0$.</p>
<i>kl</i>	<p>INTEGER. The number of subdiagonals within the band of A; $kl \geq 0$.</p>
<i>ku</i>	<p>INTEGER. The number of superdiagonals within the band of A; $ku \geq 0$.</p>
<i>ab, afb, work</i>	<p>COMPLEX for <code>cla_gbrcond_c</code></p> <p>DOUBLE COMPLEX for <code>zla_gbrcond_c</code></p> <p>Arrays:</p> <p><i>ab</i>(<i>ldab</i>,*) contains the original band matrix A stored in rows from 1 to $kl + ku + 1$. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows:</p> $ab(ku+1+i-j, j) = A(i, j)$ <p>for</p> $\max(1, j-ku) \leq i \leq \min(n, j+kl)$ <p><i>afb</i>(<i>ldaafb</i>,*) contains details of the LU factorization of the band matrix A, as returned by <code>?gbtrf</code>. U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$.</p> <p><i>work</i> is a workspace array of DIMENSION (5*n).</p> <p>The second dimension of <i>ab</i> and <i>afb</i> must be at least $\max(1, n)$.</p>
<i>ldab</i>	<p>INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq kl+ku+1$.</p>
<i>ldaafb</i>	<p>INTEGER. The leading dimension of <i>afb</i>. $ldaafb \geq 2*kl+ku+1$.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array with DIMENSION n. The pivot indices from the factorization $A = P*L*U$ as computed by <code>?gbtrf</code>. Row i of the matrix was interchanged with row <i>ipiv</i>(i).</p>
<i>c, rwork</i>	<p>REAL for <code>cla_gbrcond_c</code></p> <p>DOUBLE PRECISION for <code>zla_gbrcond_c</code></p> <p>Array <i>c</i> with DIMENSION n. The vector c in the formula</p> $\text{op}(A) * \text{inv}(\text{diag}(c)).$

Array *rwork* with `DIMENSION`*n* is a workspace.

capply LOGICAL. If `.TRUE.`, then the function uses the vector *c* from the formula $\text{op}(A) * \text{inv}(\text{diag}(c))$.

Output Parameters

info INTEGER.
If *info* = 0, the execution is successful.
If *i* > 0, the *i*-th parameter is invalid.

?la_gbrcond_x

Computes the infinity norm condition number of $\text{op}(A)\text{diag}(x)$ for general banded matrices.*

Syntax

```
call cla_gbrcond_x( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, x, info, work,
rwork )
```

```
call zla_gbrcond_x( trans, n, kl, ku, ab, ldab, afb, ldafb, ipiv, x, info, work,
rwork )
```

Include Files

- mkl.fi

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the *x* is a COMPLEX vector for `cla_gbrcond_x` and a DOUBLE COMPLEX vector for `zla_gbrcond_x`.

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
Specifies the form of the system of equations:
If *trans* = 'N', the system has the form $A*X = B$ (No transpose)
If *trans* = 'T', the system has the form $A^T*X = B$ (Transpose)
If *trans* = 'C', the system has the form $A^H*X = B$ (Conjugate Transpose = Transpose)

n INTEGER. The number of linear equations, that is, the order of the matrix *A*; $n \geq 0$.

kl INTEGER. The number of subdiagonals within the band of *A*; $kl \geq 0$.

ku INTEGER. The number of superdiagonals within the band of *A*; $ku \geq 0$.

ab, *afb*, *x*, *work* COMPLEX for `cla_gbrcond_x`
 DOUBLE COMPLEX for `zla_gbrcond_x`

Arrays:

ab(*ldab*,*) contains the original band matrix *A* stored in rows from 1 to *kl* + *ku* + 1. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:

$$ab(ku+1+i-j, j) = A(i, j)$$

for

$$\max(1, j-ku) \leq i \leq \min(n, j+kl)$$

afb(*ldafb*,*) contains details of the LU factorization of the band matrix *A*, as returned by `?gbtrf`. *U* is stored as an upper triangular band matrix with *kl*+*ku* superdiagonals in rows 1 to *kl*+*ku*+1, and the multipliers used during the factorization are stored in rows *kl*+*ku*+2 to 2**kl*+*ku*+1.

x, DIMENSION *n*. The vector *x* in the formula $op(A) * diag(x)$.

work is a workspace array of DIMENSION (2**n*).

The second dimension of *ab* and *afb* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*. *ldab* ≥ *kl*+*ku*+1.

ldafb INTEGER. The leading dimension of *afb*. *ldafb* ≥ 2**kl*+*ku*+1.

ipiv INTEGER.

Array with DIMENSION *n*. The pivot indices from the factorization $A = P*L*U$ as computed by `?gbtrf`. Row *i* of the matrix was interchanged with row *ipiv*(*i*).

rwork REAL for `cla_gbrcond_x`
 DOUBLE PRECISION for `zla_gbrcond_x`

Array *rwork* with DIMENSION *n* is a workspace.

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If *i* > 0, the *i*-th parameter is invalid.

Description

The `?la_gbrfsx_extended` subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?gbrfsx` routine calls `?la_gbrfsx_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use `?la_gbrfsx_extended` to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

<i>prec_type</i>	INTEGER. Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code> , where <code>p</code> is a CHARACTER and: If <code>p = 'S'</code> : Single. If <code>p = 'D'</code> : Double. If <code>p = 'I'</code> : Indigenous. If <code>p = 'X', 'E'</code> : Extra.
<i>trans_type</i>	INTEGER. Specifies the transposition operation on <code>A</code> . The value is defined by <code>ilatrans(t)</code> , where <code>t</code> is a CHARACTER and: If <code>t = 'N'</code> : No transpose. If <code>t = 'T'</code> : Transpose. If <code>t = 'C'</code> : Conjugate Transpose.

<i>n</i>	INTEGER. The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i> .
<i>ab, afb, b, y</i>	<p>REAL for sla_gbrfsx_extended DOUBLE PRECISION for dla_gbrfsx_extended COMPLEX for cla_gbrfsx_extended DOUBLE COMPLEX for zla_gbrfsx_extended.</p> <p>Arrays: <i>ab</i>(<i>ldab</i>,*), <i>afb</i>(<i>ldafb</i>,*), <i>b</i>(<i>ldb</i>,*), <i>y</i>(<i>ldy</i>,*).</p> <p>The array <i>ab</i> contains the original <i>n</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>ab</i> must be at least $\max(1, n)$.</p> <p>The array <i>afb</i> contains the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ as computed by ?gbtrf. The second dimension of <i>afb</i> must be at least $\max(1, n)$.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.</p> <p>The array <i>y</i> on entry contains the solution matrix <i>X</i> as computed by ?gbtrs. The second dimension of <i>y</i> must be at least $\max(1, nrhs)$.</p>
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $ldab \geq \max(1, n)$.
<i>ldafb</i>	INTEGER. The leading dimension of the array <i>afb</i> ; $ldafb \geq \max(1, n)$.
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices from the factorization $A = P * L * U$ as computed by ?gbtrf; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i>(<i>i</i>).</p>
<i>colequ</i>	LOGICAL. If <i>colequ</i> = .TRUE., column equilibration was done to <i>A</i> before calling this routine. This is needed to compute the solution and error bounds correctly.
<i>c</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p> <p><i>c</i> contains the column scale factors for <i>A</i>. If <i>colequ</i> = .FALSE., <i>c</i> is not accessed.</p> <p>If <i>c</i> is input, each element of <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p>

ldb INTEGER. The leading dimension of the array *b*; $ldb \geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; $ldy \geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

If $n_norms \geq 1$, returns normwise error bounds.

If $n_norms \geq 2$, returns componentwise error bounds.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION(*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm*(:, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition

numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION(*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then `err_bnds_comp` is not accessed. If *n_err_bnds* < 3, then at most the first (*:,n_err_bnds*) entries are returned.

The first index in `err_bnds_comp(i,:)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:,err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold

$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1 / z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

res, dy, y_tail

REAL for `sla_gbrfsx_extended`
 DOUBLE PRECISION for `dla_gbrfsx_extended`
 COMPLEX for `cla_gbrfsx_extended`
 DOUBLE COMPLEX for `zla_gbrfsx_extended`.

Workspace arrays of DIMENSION n .

res holds the intermediate residual.

dy holds the intermediate solution.

y_tail holds the trailing bits of the intermediate solution.

ayb

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION n .

rcond

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

rthresh

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < rthresh * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Determines when to start considering componentwise convergence.

Componentwise *dz_ub* convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If `.TRUE.`, the function ignores componentwise convergence. Default value is `.FALSE.`

Output Parameters

y

REAL for `sla_gbrfsx_extended`

DOUBLE PRECISION for `dla_gbrfsx_extended`

COMPLEX for `cla_gbrfsx_extended`

DOUBLE COMPLEX for `zla_gbrfsx_extended`.

The improved solution matrix Y .

berr_out

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for right-hand-side j from the formula

$\max(i) \left(\text{abs}(\text{res}(i)) / \left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right) (i) \right)$

where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z . This is computed by `?la_lin_berr`.

err_bnds_norm,
err_bnds_comp

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array $(1:nrhs, 2)$. The other elements are kept unchanged.

info

INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = $-i$, the i -th parameter had an illegal value.

?la_gbrpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a general band matrix.

Syntax

```
call sla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call dla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call cla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
call zla_gbrpvgrw( n, kl, ku, ncols, ab, ldab, afb, ldafb )
```

Include Files

- mkl.fi

Description

The ?la_gbrpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the *LU* factorization of the equilibrated matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<i>n</i>	INTEGER. The number of linear equations, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ncols</i>	INTEGER. The number of columns of the matrix <i>A</i> ; $ncols \geq 0$.
<i>ab, afb</i>	<p>REAL for sla_gbrpvgrw DOUBLE PRECISION for dla_gbrpvgrw COMPLEX for cla_gbrpvgrw DOUBLE COMPLEX for zla_gbrpvgrw.</p> <p>Arrays: <i>ab</i>(<i>ldab</i>,*), <i>afb</i>(<i>ldafb</i>,*).</p> <p><i>ab</i> contains the original band matrix <i>A</i> (see Matrix Storage Schemes) stored in rows from 1 to <i>kl</i> + <i>ku</i> + 1. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows:</p> $ab(ku+1+i-j, j) = A(i, j)$ <p>for</p> $\max(1, j-ku) \leq i \leq \min(n, j+kl)$

afb contains details of the LU factorization of the band matrix *A*, as returned by `?gbtrf`. *U* is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$.

ldab

INTEGER. The leading dimension of *ab*; $ldab \geq kl+ku+1$.

ldaafb

INTEGER. The leading dimension of *afb*; $ldaafb \geq 2*kl+ku+1$.

?la_geamv

Computes a matrix-vector product using a general matrix to calculate error bounds.

Syntax

```
call sla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call dla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call cla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call zla_geamv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- `mkl.fi`

Description

The `?la_geamv` routines perform a matrix-vector operation defined as

$$y := \alpha * \text{abs}(A) * (x) + \beta * \text{abs}(y),$$

or

$$y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y),$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

trans

CHARACTER*1. Specifies the operation:

if *trans* = BLAS_NO_TRANS, then $y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y)$

	<p>if $trans = \text{BLAS_TRANS}$, then $y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y)$</p> <p>if $trans = \text{'BLAS_CONJ_TRANS'}$, then $y := \alpha * \text{abs}(A^T) * \text{abs}(x) + \beta * \text{abs}(y)$.</p>
m	<p>INTEGER. Specifies the number of rows of the matrix A. The value of m must be at least zero.</p>
n	<p>INTEGER. Specifies the number of columns of the matrix A. The value of n must be at least zero.</p>
α	<p>REAL for <code>sla_geamv</code> and for <code>cla_geamv</code></p> <p>DOUBLE PRECISION for <code>dla_geamv</code> and <code>zla_geamv</code></p> <p>Specifies the scalar α.</p>
a	<p>REAL for <code>sla_geamv</code></p> <p>DOUBLE PRECISION for <code>dla_geamv</code></p> <p>COMPLEX for <code>cla_geamv</code></p> <p>DOUBLE COMPLEX for <code>zla_geamv</code></p> <p>Array, DIMENSION($lda, *$). Before entry, the leading m-by-n part of the array a must contain the matrix of coefficients. The second dimension of a must be at least $\max(1, n)$.</p>
lda	<p>INTEGER. Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.</p>
x	<p>REAL for <code>sla_geamv</code></p> <p>DOUBLE PRECISION for <code>dla_geamv</code></p> <p>COMPLEX for <code>cla_geamv</code></p> <p>DOUBLE COMPLEX for <code>zla_geamv</code></p> <p>Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$ when $trans = \text{'N'}$ or 'n' and at least $(1 + (m - 1) * \text{abs}(\text{incx}))$ otherwise. Before entry, the incremented array x must contain the vector X.</p>
incx	<p>INTEGER. Specifies the increment for the elements of x.</p> <p>The value of incx must be non-zero.</p>
β	<p>REAL for <code>sla_geamv</code> and for <code>cla_geamv</code></p> <p>DOUBLE PRECISION for <code>dla_geamv</code> and <code>zla_geamv</code></p> <p>Specifies the scalar β. When β is zero, you do not need to set y on input.</p>
y	<p>REAL for <code>sla_geamv</code> and for <code>cla_geamv</code></p> <p>DOUBLE PRECISION for <code>dla_geamv</code> and <code>zla_geamv</code></p> <p>Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incy}))$ when $trans = \text{'N'}$ or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with non-zero β, the incremented array y must contain the vector Y.</p>

incy INTEGER. Specifies the increment for the elements of *y*.
The value of *incy* must be non-zero.

Output Parameters

y Updated vector *Y*.

?la_gercond

Estimates the Skeel condition number for a general matrix.

Syntax

```
call sla_gercond( trans, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
call dla_gercond( trans, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
```

Include Files

- mkl.fi

Description

The function estimates the Skeel condition number of

$\text{op}(A) * \text{op2}(C)$

where

the *cmode* parameter determines *op2* as follows:

<i>cmode</i> Value	<i>op2</i> (<i>C</i>)
1	<i>C</i>
0	<i>I</i>
-1	$\text{inv}(C)$

The Skeel condition number

$\text{cond}(A) = \text{norminf}(|\text{inv}(A)| |A|)$

is computed by computing scaling factors *R* such that

$\text{diag}(R) * A * \text{op2}(C)$

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
Specifies the form of the system of equations:
If *trans* = 'N', the system has the form $A * X = B$ (No transpose).
If *trans* = 'T', the system has the form $A^T * X = B$ (Transpose).
If *trans* = 'C', the system has the form $A^H * X = B$ (Conjugate Transpose = Transpose).

<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i> , <i>af</i> , <i>c</i> , <i>work</i>	REAL for sla_gercond DOUBLE PRECISION for dla_gercond Arrays: <i>a</i> (<i>lda</i> ,*) contains the original general <i>n</i> -by- <i>n</i> matrix <i>A</i> . <i>af</i> (<i>ldaf</i> ,*) contains factors <i>L</i> and <i>U</i> from the factorization of the general matrix $A = P * L * U$, as returned by ?getrf. <i>c</i> , DIMENSION <i>n</i> . The vector <i>C</i> in the formula $\text{op}(A) * \text{op2}(C)$. <i>work</i> is a workspace array of DIMENSION (3* <i>n</i>). The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> . $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array with DIMENSION <i>n</i> . The pivot indices from the factorization $A = P * L * U$ as computed by ?getrf. Row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>cmode</i>	INTEGER. Determines $\text{op2}(C)$ in the formula $\text{op}(A) * \text{op2}(C)$ as follows: If <i>cmode</i> = 1, $\text{op2}(C) = C$. If <i>cmode</i> = 0, $\text{op2}(C) = I$. If <i>cmode</i> = -1, $\text{op2}(C) = \text{inv}(C)$.
<i>iwork</i>	INTEGER. Workspace array with DIMENSION <i>n</i> .

Output Parameters

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>i</i> > 0, the <i>i</i> -th parameter is invalid.

?la_gercond_x

Computes the infinity norm condition number of $\text{op}(A)\text{diag}(x)$ for general matrices.*

Syntax

call cla_gercond_x(*trans*, *n*, *a*, *lda*, *af*, *ldaf*, *ipiv*, *x*, *info*, *work*, *rwork*)

call zla_gercond_x(*trans*, *n*, *a*, *lda*, *af*, *ldaf*, *ipiv*, *x*, *info*, *work*, *rwork*)

Include Files

- mkl.fi

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{diag}(x)$

where the *x* is a COMPLEX vector for cla_gercond_x and a DOUBLE COMPLEX vector for zla_gercond_x.

Input Parameters

trans

CHARACTER*1. Must be 'N' or 'T' or 'C'.

Specifies the form of the system of equations:

If *trans* = 'N', the system has the form $A*X = B$ (No transpose)

If *trans* = 'T', the system has the form $A^T*X = B$ (Transpose)

If *trans* = 'C', the system has the form $A^H*X = B$ (Conjugate Transpose = Transpose)

n

INTEGER. The number of linear equations, that is, the order of the matrix *A*; $n \geq 0$.

a, *af*, *x*, *work*

COMPLEX for cla_gercond_x

DOUBLE COMPLEX for zla_gercond_x

Arrays:

a(*lda*,*) contains the original general *n*-by-*n* matrix *A*.

af(*ldaf*,*) contains the factors *L* and *U* from the factorization $A=P*L*U$ as returned by ?getrf.

x, DIMENSION *n*. The vector *x* in the formula $\text{op}(A) * \text{diag}(x).$

work is a workspace array of DIMENSION $(2*n)$.

The second dimension of *a* and *af* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of *af*. $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array with DIMENSION n . The pivot indices from the factorization $A = P*L*U$ as computed by ?getrf. Row *i* of the matrix was interchanged with row *ipiv(i)*.

rwork REAL for cla_gercond_x

DOUBLE PRECISION for zla_gercond_x

Array *rwork* with DIMENSION n is a workspace.

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If *i* > 0, the *i*-th parameter is invalid.

Description

The `?la_gersx_extended` subroutine improves the computed solution to a system of linear equations for general matrices by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?gersx` routine calls `?la_gersx_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `errs_n` and `errs_c` for details of the error bounds.

Use `?la_gersx_extended` to set only the second fields of `errs_n` and `errs_c`.

Input Parameters

<code>prec_type</code>	<p>INTEGER.</p> <p>Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code>, where <code>p</code> is a CHARACTER and:</p> <p>If <code>p = 'S'</code>: Single.</p> <p>If <code>p = 'D'</code>: Double.</p> <p>If <code>p = 'I'</code>: Indigenous.</p> <p>If <code>p = 'X', 'E'</code>: Extra.</p>
<code>trans_type</code>	<p>INTEGER.</p> <p>Specifies the transposition operation on <i>A</i>. The value is defined by <code>ilatrans(t)</code>, where <code>t</code> is a CHARACTER and:</p> <p>If <code>t = 'N'</code>: No transpose.</p> <p>If <code>t = 'T'</code>: Transpose.</p> <p>If <code>t = 'C'</code>: Conjugate Transpose.</p>
<code>n</code>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<code>nrhs</code>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i>.</p>
<code>a, af, b, y</code>	<p>REAL for <code>sla_gersx_extended</code></p> <p>DOUBLE PRECISION for <code>dla_gersx_extended</code></p> <p>COMPLEX for <code>cla_gersx_extended</code></p> <p>DOUBLE COMPLEX for <code>zla_gersx_extended</code>.</p> <p>Arrays: <code>a(lda,*)</code>, <code>af(ldaf,*)</code>, <code>b(ldb,*)</code>, <code>y(ldy,*)</code>.</p> <p>The array <i>a</i> contains the original matrix <i>n</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least <code>max(1,n)</code>.</p> <p>The array <i>af</i> contains the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ as computed by <code>?getrf</code>. The second dimension of <i>af</i> must be at least <code>max(1,n)</code>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least <code>max(1,nrhs)</code>.</p>

The array *y* on entry contains the solution matrix *X* as computed by ?getrs. The second dimension of *y* must be at least $\max(1, nrhs)$.

lda INTEGER. The leading dimension of the array *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*; $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices from the factorization $A = P*L*U$ as computed by ?getrf; row *i* of the matrix was interchanged with row *ipiv(i)*.

colequ LOGICAL. If *colequ* = .TRUE., column equilibration was done to *A* before calling this routine. This is needed to compute the solution and error bounds correctly.

c REAL for single precision flavors (sla_gersx_extended, cla_gersx_extended)
DOUBLE PRECISION for double precision flavors (dla_gersx_extended, zla_gersx_extended).

c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not used.

If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array *b*; $ldb \geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; $ldy \geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *errs_n* and *errs_c* descriptions in *Output Arguments* section below.

If $n_norms \geq 1$, returns normwise error bounds.

If $n_norms \geq 2$, returns componentwise error bounds.

errs_n REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION(*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `errs_n(i,:)` corresponds to the i -th right-hand side.

The second index in `errs_n(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.

`errs_c`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION(`nrhs`, `n_err_bnds`). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for

each right-hand side. If componentwise accuracy is not requested ($params(3) = 0.0$), then $errs_c$ is not accessed. If $n_err_bnds < 3$, then at most the first $(:,n_err_bnds)$ entries are returned.

The first index in $errs_c(i,:)$ corresponds to the i -th right-hand side.

The second index in $errs_c(:,err)$ contains the following three fields:

$err=1$	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.
$err=2$	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
$err=3$	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.

res, dy, y_tail

REAL for `sla_gersx_extended`
DOUBLE PRECISION for `dla_gersx_extended`
COMPLEX for `cla_gersx_extended`
DOUBLE COMPLEX for `zla_gersx_extended`.

Workspace arrays of DIMENSION n .

res holds the intermediate residual.

dy holds the intermediate solution.

y_tail holds the trailing bits of the intermediate solution.

ayb

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, `DIMENSIONn`.

rcond

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in *errs_n* and *errs_c* may no longer be trustworthy.

rthresh

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$$\text{norm}(\text{dx}_{\{i+1\}}) < rthresh * \text{norm}(\text{dx}_i)$$

where $\text{norm}(z)$ is the infinity norm of *Z*.

rthresh satisfies

$$0 < rthresh \leq 1.$$

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Determines when to start considering componentwise convergence. Componentwise *dz_ub* convergence is only considered after each component of the solution *y* is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If `.TRUE.`, the function ignores componentwise convergence. Default value is `.FALSE.`

Output Parameters

y

REAL for `sla_gerfsx_extended`

DOUBLE PRECISION for `dla_gerfsx_extended`

COMPLEX for `cla_gerfsx_extended`

DOUBLE COMPLEX for `zla_gerfsx_extended`.

	The improved solution matrix Y .
<code>berr_out</code>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for right-hand-side j from the formula</p> $\max(i) \left(\frac{\text{abs}(\text{res}(i))}{\left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right) (i)} \right)$ <p>where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z. This is computed by <code>?la_lin_berr</code>.</p>
<code>errs_n, errs_c</code>	<p>Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array $(1:nrhs, 2)$. The other elements are kept unchanged.</p>
<code>info</code>	<p>INTEGER. If <code>info = 0</code>, the execution is successful. The solution to every right-hand side is guaranteed.</p> <p>If <code>info = -i</code>, the i-th parameter had an illegal value.</p>

?la_heamv

Computes a matrix-vector product using a Hermitian indefinite matrix to calculate error bounds.

Syntax

```
call cla_heamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call zla_heamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- `mkl.fi`

Description

The `?la_heamv` routines perform a matrix-vector operation defined as

$$y := \alpha * \text{abs}(A) * \text{abs}(x) + \beta * \text{abs}(y),$$

where:

α and β are scalars,

x and y are vectors,

A is an n -by- n Hermitian matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array A is to be referenced: If <i>uplo</i> = 'BLAS_UPPER', only the upper triangular part of A is to be referenced, If <i>uplo</i> = 'BLAS_LOWER', only the lower triangular part of A is to be referenced.
<i>n</i>	INTEGER. Specifies the number of rows and columns of the matrix A. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>cla_heamv</i> DOUBLE PRECISION for <i>zla_heamv</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for <i>cla_heamv</i> DOUBLE COMPLEX for <i>zla_heamv</i> Array, DIMENSION(<i>lda</i> , *). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	COMPLEX for <i>cla_heamv</i> DOUBLE COMPLEX for <i>zla_heamv</i> Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>X</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must be non-zero.
<i>beta</i>	REAL for <i>cla_heamv</i> DOUBLE PRECISION for <i>zla_heamv</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is zero, you do not need to set <i>y</i> on input.
<i>y</i>	REAL for <i>cla_heamv</i> DOUBLE PRECISION for <i>zla_heamv</i>

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with non-zero *beta*, the incremented array *y* must contain the vector *Y*.

incy INTEGER. Specifies the increment for the elements of *y*.
The value of *incy* must be non-zero.

Output Parameters

y Updated vector *Y*.

?la_hercond_c

*Computes the infinity norm condition number of $\text{op}(A) * \text{inv}(\text{diag}(c))$ for Hermitian indefinite matrices.*

Syntax

```
call cla_hercond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
call zla_hercond_c( uplo, n, a, lda, af, ldaf, ipiv, c, capply, info, work, rwork )
```

Include Files

- mkl.fi

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{inv}(\text{diag}(c))$

where the *c* is a REAL vector for `cla_hercond_c` and a DOUBLE PRECISION vector for `zla_hercond_c`.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Specifies the triangle of *A* to store:
If *uplo* = 'U', the upper triangle of *A* is stored,
If *uplo* = 'L', the lower triangle of *A* is stored.

n INTEGER. The number of linear equations, that is, the order of the matrix *A*; $n \geq 0$.

a COMPLEX for `cla_hercond_c`
DOUBLE COMPLEX for `zla_hercond_c`
Array, DIMENSION(*lda*, *). On entry, the *n*-by-*n* matrix *A*. The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

af COMPLEX for `cla_hercond_c`
DOUBLE COMPLEX for `zla_hercond_c`

Array, `DIMENSION(ldaf, *)`. The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by `?hetrf`. The second dimension of af must be at least $\max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*. $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array with `DIMENSIONn`. Details of the interchanges and the block structure of D as determined by `?hetrf`.

c REAL for `cla_hercond_c`
DOUBLE PRECISION for `zla_hercond_c`
Array *c* with `DIMENSIONn`. The vector *c* in the formula
$$\text{op}(A) * \text{inv}(\text{diag}(c)).$$

capply LOGICAL. If `.TRUE.`, then the function uses the vector *c* from the formula
$$\text{op}(A) * \text{inv}(\text{diag}(c)).$$

work COMPLEX for `cla_hercond_c`
DOUBLE COMPLEX for `zla_hercond_c`
Array `DIMENSION 2*n`. Workspace.

rwork REAL for `cla_hercond_c`
DOUBLE PRECISION for `zla_hercond_c`
Array `DIMENSIONn`. Workspace.

Output Parameters

info INTEGER.
If *info* = 0, the execution is successful.
If *i* > 0, the *i*-th parameter is invalid.

See Also

`?hetrf`

?la_hercond_x

*Computes the infinity norm condition number of $\text{op}(A) * \text{diag}(x)$ for Hermitian indefinite matrices.*

Syntax

```
call cla_hercond_x( uplo, n, a, lda, af, ldaf, ipiv, x, info, work, rwork )

Include Files

- mkl.fi

Description

The ?la_herfsx_extended subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The ?herfsx routine calls ?la_herfsx_extended to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

Use ?la_herfsx_extended to set only the second fields of *err_bnds_norm* and *err_bnds_comp*.

Input Parameters

prec_type INTEGER.
 Specifies the intermediate precision to be used in refinement. The value is defined by *ilaprec(p)*, where *p* is a CHARACTER and:
 If *p* = 'S': Single.
 If *p* = 'D': Double.
 If *p* = 'I': Indigenous.
 If *p* = 'X', 'E': Extra.

uplo CHARACTER*1. Must be 'U' or 'L'.
 Specifies the triangle of A to store:

	<p>If <code>uplo = 'U'</code>, the upper triangle of A is stored,</p> <p>If <code>uplo = 'L'</code>, the lower triangle of A is stored.</p>
<code>n</code>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the matrix B .
<code>a, af, b, y</code>	<p>COMPLEX for <code>cla_herfsx_extended</code></p> <p>DOUBLE COMPLEX for <code>zla_herfsx_extended</code>.</p> <p>Arrays: <code>a(lda,*)</code>, <code>af(ldaf,*)</code>, <code>b ldb,*)</code>, <code>y(ldy,*)</code>.</p> <p>The array <code>a</code> contains the original n-by-n matrix A. The second dimension of <code>a</code> must be at least <code>max(1,n)</code>.</p> <p>The array <code>af</code> contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?hetrf</code>. The second dimension of <code>af</code> must be at least <code>max(1,n)</code>.</p> <p>The array <code>b</code> contains the right-hand-side of the matrix B. The second dimension of <code>b</code> must be at least <code>max(1,nrhs)</code>.</p> <p>The array <code>y</code> on entry contains the solution matrix X as computed by <code>?hetrs</code>. The second dimension of <code>y</code> must be at least <code>max(1,nrhs)</code>.</p>
<code>lda</code>	INTEGER. The leading dimension of the array <code>a</code> ; <code>lda</code> \geq <code>max(1,n)</code> .
<code>ldaf</code>	INTEGER. The leading dimension of the array <code>af</code> ; <code>ldaf</code> \geq <code>max(1,n)</code> .
<code>ipiv</code>	<p>INTEGER.</p> <p>Array, DIMENSION <code>n</code>. Details of the interchanges and the block structure of D as determined by <code>?hetrf</code>.</p>
<code>colequ</code>	LOGICAL. If <code>colequ = .TRUE.</code> , column equilibration was done to A before calling this routine. This is needed to compute the solution and error bounds correctly.
<code>c</code>	<p>REAL for <code>cla_herfsx_extended</code></p> <p>DOUBLE PRECISION for <code>zla_herfsx_extended</code>.</p> <p><code>c</code> contains the column scale factors for A. If <code>colequ = .FALSE.</code>, <code>c</code> is not used.</p> <p>If <code>c</code> is input, each element of <code>c</code> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p>
<code>ldb</code>	INTEGER. The leading dimension of the array <code>b</code> ; <code>ldb</code> \geq <code>max(1, nrhs)</code> .
<code>ldy</code>	INTEGER. The leading dimension of the array <code>y</code> ; <code>ldy</code> \geq <code>max(1, nrhs)</code> .
<code>n_norms</code>	INTEGER. Determines which error bounds to return. See <code>err_bnds_norm</code> and <code>err_bnds_comp</code> descriptions in <i>Output Arguments</i> section below.

If $n_norms \geq 1$, returns normwise error bounds.

If $n_norms \geq 2$, returns componentwise error bounds.

err_bnds_norm

REAL for *cla_herfsx_extended*

DOUBLE PRECISION for *zla_herfsx_extended*.

Array, DIMENSION(*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.

Normwise relative error in the i -th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*($i, :$) corresponds to the i -th right-hand side.

The second index in *err_bnds_norm*($:, err$) contains the following three fields:

<i>err</i> =1	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cla_herfsx_extended</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zla_herfsx_extended</i> .
<i>err</i> =2	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cla_herfsx_extended</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zla_herfsx_extended</i> . This error bound should only be trusted if the previous boolean is true.
<i>err</i> =3	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>cla_herfsx_extended</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zla_herfsx_extended</i> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Array, `DIMENSION(nrhs, n_err_bnds)`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If `n_err_bnds < 3`, then at most the first `(:, n_err_bnds)` entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

`err=1`

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold `sqrt(n)*slamch(ε)` for `cla_herfsx_extended` and `sqrt(n)*dlamch(ε)` for `zla_herfsx_extended`.

`err=2`

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold `sqrt(n)*slamch(ε)` for `cla_herfsx_extended` and `sqrt(n)*dlamch(ε)` for `zla_herfsx_extended`. This error bound should only be trusted if the previous boolean is true.

`err=3`

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold `sqrt(n)*slamch(ε)` for

`cla_herfsx_extended` and `sqrt(n)*dlamch(ε)` for `zla_herfsx_extended` to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

res, dy, y_tail

COMPLEX for `cla_herfsx_extended`

DOUBLE COMPLEX for `zla_herfsx_extended`.

Workspace arrays of DIMENSION n .

res holds the intermediate residual.

dy holds the intermediate solution.

y_tail holds the trailing bits of the intermediate solution.

ayb

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Workspace array, DIMENSION n .

rcond

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

rthresh

REAL for `cla_herfsx_extended`

DOUBLE PRECISION for `zla_herfsx_extended`.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for *cla_herfsx_extended*

DOUBLE PRECISION for *zla_herfsx_extended*.

Determines when to start considering componentwise convergence. Componentwise *dz_ub* convergence is only considered after each component of the solution *y* is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If *.TRUE.*, the function ignores componentwise convergence. Default value is *.FALSE.*

Output Parameters

y

COMPLEX for *cla_herfsx_extended*

DOUBLE COMPLEX for *zla_herfsx_extended*.

The improved solution matrix *Y*.

berr_out

REAL for *cla_herfsx_extended*

DOUBLE PRECISION for *zla_herfsx_extended*.

Array, DIMENSION *nrhs*. *berr_out(j)* contains the componentwise relative backward error for right-hand-side *j* from the formula

$$\max(i) \left(\text{abs}(\text{res}(i)) / \left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right) (i) \right)$$

where *abs(z)* is the componentwise absolute value of the matrix or vector *Z*. This is computed by *?la_lin_berr*.

err_bnds_norm,
err_bnds_comp

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array (*1:nrhs*, 2). The other elements are kept unchanged.

info

INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = *-i*, the *i*-th parameter had an illegal value.

?la_herpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a Hermitian indefinite matrix.

Syntax

```
call cla_herpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call zla_herpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
```

Include Files

- mkl.fi

Description

The ?la_herpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the equilibrated matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>info</i>	INTEGER. The value of INFO returned from ?hetrf, that is, the pivot in column <i>info</i> is exactly 0.
<i>a, af</i>	COMPLEX for cla_herpvgrw DOUBLE COMPLEX for zla_herpvgrw. Arrays: <i>a</i> (<i>lda</i> ,*), <i>af</i> (<i>ldaf</i> ,*). <i>a</i> contains the <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>af</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?hetrf. The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of array <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of array <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION <i>n</i> . Details of the interchanges and the block structure of <i>D</i> as determined by ?hetrf.
<i>work</i>	REAL for cla_herpvgrw

DOUBLE PRECISION for zla_herpvgrw.

Array, DIMENSION 2*n. Workspace.

```

```
call zla_lin_berr(n, nz, nrhs, res, ayb, berr )
```

Include Files

- mkl.fi

Description

The ?la_lin_berr computes a component-wise relative backward error from the formula:

$$\max(i) \left(\frac{\text{abs}(R(i))}{(\text{abs}(\text{op}(A_s)) * \text{abs}(Y) + \text{abs}(B_s)) (i)} \right)$$

where $\text{abs}(Z)$ is the component-wise value of the matrix or vector Z .

Input Parameters

<i>n</i>	INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.
<i>nz</i>	INTEGER. The parameter for guarding against spuriously zero residuals. $(nz+1) * \text{slamch}(' \text{Safe minimum}')$ is added to $R(i)$ in the numerator of the relative backward error formula. The default value is n .
<i>nrhs</i>	INTEGER. Number of right-hand sides, the number of columns in the matrices AYB , RES , and $BERR$; $nrhs \geq 0$.
<i>res, ayb</i>	REAL for sla_lin_berr, cla_lin_berr DOUBLE PRECISION for dla_lin_berr, zla_lin_berr Arrays, DIMENSION ($n, nrhs$). <i>res</i> is the residual matrix, that is, the matrix R in the relative backward error formula. <i>ayb</i> is the denominator of that formula, that is, the matrix $\text{abs}(\text{op}(A_s)) * \text{abs}(Y) + \text{abs}(B_s)$. The matrices A , Y , and B are from iterative refinement. See description of ?la_gersfx_extended.

Output Parameters

berr REAL for sla_lin_berr

DOUBLE PRECISION for dla_lin_berr
COMPLEX for cla_lin_berr
DOUBLE COMPLEX for zla_lin_berr
The component-wise relative backward error.

?la_porcond
Estimates the Skeel condition number for a symmetric positive-definite matrix.

Syntax
call sla_porcond(uplo, n, a, lda, af, ldaf, cmode, c, info, work, iwork)
call dla_porcond(uplo, n, a, lda, af, ldaf, cmode, c, info, work, iwork)

Include Files
• mkl.fi

Description
The function estimates the Skeel condition number of
$$\text{op}(A) * \text{op2}(C)$$
where
the *cmode* parameter determines *op2* as follows:

<i>cmode</i> Value	op2(C)
1	<i>C</i>
0	<i>I</i>
-1	inv(<i>C</i>)

The Skeel condition number
$$\text{cond}(A) = \text{norminf}(|\text{inv}(A)| |A|)$$
is computed by computing scaling factors *R* such that
$$\text{diag}(R) * A * \text{op2}(C)$$
is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters
uplo CHARACTER*1. Must be 'U' or 'L'.
Specifies the triangle of A to store:
If *uplo* = 'U', the upper triangle of A is stored,
If *uplo* = 'L', the lower triangle of A is stored.

<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i> , <i>af</i> , <i>c</i> , <i>work</i>	REAL for sla_porcond DOUBLE PRECISION for dla_porcond Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix <i>A</i> . <i>af</i> (<i>ldaf</i> ,*) contains the triangular factor <i>L</i> or <i>U</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, as computed by ?potrf. <i>c</i> , DIMENSION <i>n</i> . The vector <i>c</i> in the formula $\text{op}(A) * \text{op2}(C)$. <i>work</i> is a workspace array of DIMENSION (3* <i>n</i>). The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>ab</i> . $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> . $ldaf \geq \max(1, n)$.
<i>cmode</i>	INTEGER. Determines $\text{op2}(C)$ in the formula $\text{op}(A) * \text{op2}(C)$ as follows: If <i>cmode</i> = 1, $\text{op2}(C) = C$. If <i>cmode</i> = 0, $\text{op2}(C) = I$. If <i>cmode</i> = -1, $\text{op2}(C) = \text{inv}(C)$.
<i>iwork</i>	INTEGER. Workspace array with DIMENSION <i>n</i> .

Output Parameters

<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>i</i> > 0, the <i>i</i> -th parameter is invalid.

?la_porcond_x

*Computes the infinity norm condition number of $op(A)*diag(x)$ for Hermitian positive-definite matrices.*

Syntax

```
call cla_porcond_x( uplo, n, a, lda, af, ldaf, x, info, work, rwork )
call zla_porcond_x( uplo, n, a, lda, af, ldaf, x, info, work, rwork )
```

Include Files

- `mk1.fi`

Description

The function computes the infinity norm condition number of

$op(A) * diag(x)$

where the `x` is a COMPLEX vector for `cla_porcond_x` and a DOUBLE COMPLEX vector for `zla_porcond_x`.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.
 Specifies the triangle of *A* to store:
 If `uplo = 'U'`, the upper triangle of *A* is stored,
 If `uplo = 'L'`, the lower triangle of *A* is stored.

`n` INTEGER. The number of linear equations, that is, the order of the matrix *A*; $n \geq 0$.

`a` COMPLEX for `cla_porcond_c`
 DOUBLE COMPLEX for `zla_porcond_c`
 Array, DIMENSION(`lda`, *). On entry, the *n*-by-*n* matrix *A*.
 The second dimension of *a* must be at least $\max(1, n)$.

`lda` INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

`af` COMPLEX for `cla_porcond_c`
 DOUBLE COMPLEX for `zla_porcond_c`

Array, DIMENSION(*ldaf*, *). The triangular factor *L* or *U* from the Cholesky factorization

$$A = U^H * U \text{ or } A = L * L^H,$$

as computed by `?potrf`.

The second dimension of *af* must be at least $\max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*. $ldaf \geq \max(1, n)$.

x COMPLEX for `cla_porcond_c`

DOUBLE COMPLEX for `zla_porcond_c`

Array *x* with DIMENSION *n*. The vector *x* in the formula

$$\text{op}(A) * \text{inv}(\text{diag}(x)).$$

work COMPLEX for `cla_porcond_c`

DOUBLE COMPLEX for `zla_porcond_c`

Array DIMENSION $2*n$. Workspace.

rwork REAL for `cla_porcond_c`

DOUBLE PRECISION for `zla_porcond_c`

Array DIMENSION *n*. Workspace.

Output Parameters

info INTEGER.

If *info* = 0, the execution is successful.

If *i* > 0, the *i*-th parameter is invalid.

- mkl.fi

Description

The `?la_porfsx_extended` subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?herfsx` routine calls `?la_porfsx_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use `?la_porfsx_extended` to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

<code>prec_type</code>	<p>INTEGER.</p> <p>Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code>, where <code>p</code> is a CHARACTER and:</p> <p>If <code>p = 'S'</code>: Single.</p> <p>If <code>p = 'D'</code>: Double.</p> <p>If <code>p = 'I'</code>: Indigenous.</p> <p>If <code>p = 'X', 'E'</code>: Extra.</p>
<code>uplo</code>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies the triangle of <i>A</i> to store:</p> <p>If <code>uplo = 'U'</code>, the upper triangle of <i>A</i> is stored,</p> <p>If <code>uplo = 'L'</code>, the lower triangle of <i>A</i> is stored.</p>
<code>n</code>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<code>nrhs</code>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i>.</p>
<code>a, af, b, y</code>	<p>REAL for <code>sla_porfsx_extended</code></p> <p>DOUBLE PRECISION for <code>dla_porfsx_extended</code></p> <p>COMPLEX for <code>cla_porfsx_extended</code></p> <p>DOUBLE COMPLEX for <code>zla_porfsx_extended</code>.</p> <p>Arrays: <code>a(lda,*)</code>, <code>af(ldaf,*)</code>, <code>b(ldb,*)</code>, <code>y(ldy,*)</code>.</p> <p>The array <i>a</i> contains the original <i>n</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least <code>max(1,n)</code>.</p> <p>The array <i>af</i> contains the triangular factor <i>L</i> or <i>U</i> from the Cholesky factorization as computed by <code>?potrf</code>:</p> <p>$A = U^T * U$ or $A = L * L^T$ for real flavors,</p> <p>$A = U^H * U$ or $A = L * L^H$ for complex flavors.</p>

The second dimension of *af* must be at least $\max(1, n)$.

The array *b* contains the right-hand-side of the matrix *B*. The second dimension of *b* must be at least $\max(1, nrhs)$.

The array *y* on entry contains the solution matrix *X* as computed by ?potrs. The second dimension of *y* must be at least $\max(1, nrhs)$.

lda INTEGER. The leading dimension of the array *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*; $ldaf \geq \max(1, n)$.

colequ LOGICAL. If *colequ* = .TRUE., column equilibration was done to *A* before calling this routine. This is needed to compute the solution and error bounds correctly.

c REAL for sla_porfsx_extended and cla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended and
zla_porfsx_extended.

c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not used.

If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array *b*; $ldb \geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; $ldy \geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

If *n_norms* ≥ 1 , returns normwise error bounds.

If *n_norms* ≥ 2 , returns componentwise error bounds.

err_bnds_norm REAL for sla_porfsx_extended and cla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended and
zla_porfsx_extended.

Array, $\text{DIMENSION}(nrhs, n_err_bnds)$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.

Normwise relative error in the *i*-th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i,:)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_porfsx_extended/cla_porfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_porfsx_extended/zla_porfsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix <i>Z</i> . Let $z = s * a$, where <i>s</i> scales each row by a power of the radix so all absolute row sums of <i>z</i> are approximately 1. Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for `sla_porfsx_extended` and `cla_porfsx_extended`

DOUBLE PRECISION for `dla_porfsx_extended` and `zla_porfsx_extended`.

Array, `DIMENSION(nrhs,n_err_bnds)`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If `n_err_bnds < 3`, then at most the first `(:,n_err_bnds)` entries are returned.

The first index in `err_bnds_comp(i,:)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_porfsx_extended/cla_porfsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_porfsx_extended/zla_porfsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_porfsx_extended/cla_porfsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_porfsx_extended/zla_porfsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_porfsx_extended/cla_porfsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_porfsx_extended/zla_porfsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal

condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

res, dy, y_tail

REAL for sla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended
COMPLEX for cla_porfsx_extended
DOUBLE COMPLEX for zla_porfsx_extended.

Workspace arrays of DIMENSION n .

res holds the intermediate residual.

dy holds the intermediate solution.

y_tail holds the trailing bits of the intermediate solution.

ayb

REAL for sla_porfsx_extended and cla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended and
zla_porfsx_extended.

Workspace array, DIMENSION n .

rcond

REAL for sla_porfsx_extended and cla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended and
zla_porfsx_extended.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

rthresh

REAL for sla_porfsx_extended and cla_porfsx_extended
DOUBLE PRECISION for dla_porfsx_extended and
zla_porfsx_extended.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for *sla_porfsx_extended* and *cla_porfsx_extended*

DOUBLE PRECISION for *dla_porfsx_extended* and
zla_porfsx_extended.

Determines when to start considering componentwise convergence. Componentwise *dz_ub* convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If `.TRUE.`, the function ignores componentwise convergence. Default value is `.FALSE.`

Output Parameters

y

REAL for *sla_porfsx_extended*

DOUBLE PRECISION for *dla_porfsx_extended*

COMPLEX for *cla_porfsx_extended*

DOUBLE COMPLEX for *zla_porfsx_extended*.

The improved solution matrix Y .

berr_out

REAL for *sla_porfsx_extended* and *cla_porfsx_extended*

DOUBLE PRECISION for *dla_porfsx_extended* and
zla_porfsx_extended.

Array, DIMENSION *nrhs*. *berr_out(j)* contains the componentwise relative backward error for right-hand-side j from the formula

$$\max(i) \left(\text{abs}(\text{res}(i)) / \left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right) (i) \right)$$

where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z . This is computed by `?la_lin_berr`.

err_bnds_norm,
err_bnds_comp

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array `(1:nrhs, 2)`. The other elements are kept unchanged.

info

INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = $-i$, the i -th parameter had an illegal value.

?laqhe

Scales a Hermitian matrix.

Syntax

```
call claqhe( uplo, n, a, lda, s, scond, amax, equed )
call zlaqhe( uplo, n, a, lda, s, scond, amax, equed )
```

Include Files

- `mkl.fi`

Description

The routine equilibrates a Hermitian matrix *A* using the scaling factors in the vector *s*.

Input Parameters

uplo CHARACTER*1.
 Specifies whether to store the upper or lower part of the Hermitian matrix *A*.
 If *uplo* = 'U', the upper triangular part of *A*;
 if *uplo* = 'L', the lower triangular part of *A*.

n INTEGER. The order of the matrix *A*.
 $n \geq 0$.

a COMPLEX for *claqhe*
 DOUBLE COMPLEX for *zlaqhe*
 Array, DIMENSION (*lda*,*n*). On entry, the Hermitian matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of matrix *A* and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of matrix *A* and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*.

	$lda \geq \max(n, 1)$.
<i>s</i>	REAL for claqhe DOUBLE PRECISION for zlaqhe Array, DIMENSION (<i>n</i>). The scale factors for <i>A</i> .
<i>scond</i>	REAL for claqhe DOUBLE PRECISION for zlaqhe Ratio of the smallest <i>s(i)</i> to the largest <i>s(i)</i> .
<i>amax</i>	REAL for claqhe DOUBLE PRECISION for zlaqhe Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	If <i>equed</i> = 'Y', <i>a</i> contains the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$.
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, that is, <i>A</i> has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*. The parameter *thresh* is a threshold value used to decide if scaling should be done based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done.

The *large* and *small* parameters are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqhp

Scales a Hermitian matrix stored in packed form.

Syntax

```
call claqhp( uplo, n, ap, s, sconf, amax, equed )
call zlaqhp( uplo, n, ap, s, sconf, amax, equed )
```

Include Files

- mkl.fi

Description

Output Parameters

<i>a</i>	<p>If <i>equed</i> = 'Y', <i>a</i> contains the equilibrated matrix $\text{diag}(s) * A * \text{diag}(s)$ in the same storage format as on input.</p>
<i>equed</i>	<p>CHARACTER*1.</p> <p>Specifies whether or not equilibration was done.</p> <p>If <i>equed</i> = 'N': No equilibration.</p> <p>If <i>equed</i> = 'Y': Equilibration was done, that is, <i>A</i> has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.</p>

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*. The parameter *thresh* is a threshold value used to decide if scaling should be done based on the ratio of the scaling factors. If $scond < thresh$, scaling is done.

The *large* and *small* parameters are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?larcm

Multiplies a square real matrix by a complex matrix.

Syntax

```
call clarcm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

```
call zlarcm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Include Files

- mkl.fi

Description

The routine performs a simple matrix-matrix multiplication of the form

$$C = A * B,$$

where *A* is *m*-by-*m* and real, *B* is *m*-by-*n* and complex, *C* is *m*-by-*n* and complex.

Input Parameters

<i>m</i>	INTEGER. The number of rows and columns of the matrix <i>A</i> and of the number of rows of the matrix <i>C</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>B</i> and the number of columns of the matrix <i>C</i> ($n \geq 0$).
<i>a</i>	REAL for clarcm DOUBLE PRECISION for zlarcm Array, DIMENSION(<i>lda</i> , <i>m</i>). Contains the <i>m</i> -by- <i>m</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> , $lda \geq \max(1, m)$.
<i>b</i>	COMPLEX for clarcm DOUBLE COMPLEX for zlarcm Array, DIMENSION(<i>ldb</i> , <i>n</i>). Contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> .
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> , $ldb \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The leading dimension of the output array <i>c</i> , $ldc \geq \max(1, m)$.
<i>rwork</i>	REAL for clarcm DOUBLE PRECISION for zlarcm

Workspace array, $\text{DIMENSION}(2*m*n)$.

Output Parameters

c COMPLEX for `clarcm`
 DOUBLE COMPLEX for `zlarcm`
 Array, $\text{DIMENSION}(ldc, n)$. Contains the m -by- n matrix C .

?la_gerpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a general matrix.

Syntax

```
call sla_gerpvgrw( n, ncols, a, lda, af, ldaf )
call dla_gerpvgrw( n, ncols, a, lda, af, ldaf )
call cla_gerpvgrw( n, ncols, a, lda, af, ldaf )
call zla_gerpvgrw( n, ncols, a, lda, af, ldaf )
```

Include Files

- `mkl.fi`

Description

The `?la_gerpvgrw` routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the equilibrated matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable.

Input Parameters

n INTEGER. The number of linear equations, the order of the matrix A ; $n \geq 0$.

$ncols$ INTEGER. The number of columns of the matrix A ; $ncols \geq 0$.

a, af REAL for `sla_gerpvgrw`
 DOUBLE PRECISION for `dla_gerpvgrw`
 COMPLEX for `cla_gerpvgrw`
 DOUBLE COMPLEX for `zla_gerpvgrw`.
 Arrays: $a(lda, *)$, $af(ldaf, *)$.
 The array a contains the input n -by- n matrix A . The second dimension of a must be at least $\max(1, n)$.
 The array af contains the factors L and U from the factorization triangular factor L or U from the Cholesky factorization $A = P*L*U$ as computed by `?getrf`. The second dimension of af must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of *af*; $ldaf \geq \max(1, n)$.

?larscl2

Performs reciprocal diagonal scaling on a vector.

Syntax

```
call slarscl2(m, n, d, x, ldx)
call dlarscl2(m, n, d, x, ldx)
call clarscl2(m, n, d, x, ldx)
call zlarscl2(m, n, d, x, ldx)
```

Include Files

- mkl.fi

Description

The `?larscl2` routines perform reciprocal diagonal scaling on a vector

$$x := D^{-1} * x,$$

where:

x is a vector, and

D is a diagonal matrix.

Input Parameters

m INTEGER. Specifies the number of rows of the matrix *D* and the number of elements of the vector *x*. The value of *m* must be at least zero.

n INTEGER. The number of columns of *D* and *x*. The value of *n* must be at least zero.

d REAL for `slarscl2` and `clarscl2`.
DOUBLE PRECISION for `dlarscl2` and `zlarscl2`.
Array, DIMENSION *m*. Diagonal matrix *D* stored as a vector of length *m*.

x REAL for `slarscl2`.
DOUBLE PRECISION for `dlarscl2`.
COMPLEX for `clarscl2`.
DOUBLE COMPLEX for `zlarscl2`.
Array, DIMENSION (*ldx*, *n*). The vector *x* to scale by *D*.

ldx INTEGER.

The leading dimension of the vector x . The value of ldx must be at least zero.

Output Parameters

x Scaled vector x .

?lascl2

Performs diagonal scaling on a vector.

Syntax

```
call slascl2(m, n, d, x, ldx)
call dlascl2(m, n, d, x, ldx)
call clascl2(m, n, d, x, ldx)
call zlascl2(m, n, d, x, ldx)
```

Description

The ?lascl2 routines perform diagonal scaling on a vector

$x := D * x$,

where:

x is a vector, and

D is a diagonal matrix.

Input Parameters

m	INTEGER. Specifies the number of rows of the matrix D and the number of elements of the vector x . The value of m must be at least zero.
n	INTEGER. The number of columns of D and x . The value of n must be at least zero.
d	REAL for slascl2 and clascl2. DOUBLE PRECISION for dlascl2 and zlascl2. Array, DIMENSION m . Diagonal matrix D stored as a vector of length m .
x	REAL for slascl2. DOUBLE PRECISION for dlascl2. COMPLEX for clascl2. DOUBLE COMPLEX for zlascl2. Array, DIMENSION (ldx, n) . The vector x to scale by D .
ldx	INTEGER.

The leading dimension of the vector x . The value of ldx must be at least zero.

Output Parameters

x Scaled vector x .

?la_syamv

Computes a matrix-vector product using a symmetric indefinite matrix to calculate error bounds.

Syntax

```
call sla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call dla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call cla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call zla_syamv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Include Files

- mkl.fi

Description

The ?la_syamv routines perform a matrix-vector operation defined as

$$y := \alpha \cdot \text{abs}(A) \cdot \text{abs}(x) + \beta \cdot \text{abs}(y),$$

where:

α and β are scalars,

x and y are vectors,

A is an n -by- n Hermitian matrix.

This function is primarily used in calculating error bounds. To protect against underflow during evaluation, the function perturbs components in the resulting vector away from zero by $(n + 1)$ times the underflow threshold. To prevent unnecessarily large errors for block structure embedded in general matrices, the function does not perturb *symbolically* zero components. A zero entry is considered *symbolic* if all multiplications involved in computing that entry have at least one zero multiplicand.

Input Parameters

$uplo$	CHARACTER*1. Specifies whether the upper or lower triangular part of the array A is to be referenced: If $uplo = 'BLAS_UPPER'$, only the upper triangular part of A is to be referenced, If $uplo = 'BLAS_LOWER'$, only the lower triangular part of A is to be referenced.
n	INTEGER. Specifies the number of rows and columns of the matrix A . The value of n must be at least zero.

<i>alpha</i>	<p>REAL for <code>sla_syamv</code> and <code>cla_syamv</code></p> <p>DOUBLE PRECISION for <code>dla_syamv</code> and <code>zla_syamv</code>.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>REAL for <code>sla_syamv</code></p> <p>DOUBLE PRECISION for <code>dla_syamv</code></p> <p>COMPLEX for <code>cla_syamv</code></p> <p>DOUBLE COMPLEX for <code>zla_syamv</code>.</p> <p>Array, DIMENSION(<i>lda</i>, *). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix of coefficients. The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>
<i>lda</i>	<p>INTEGER. Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.</p>
<i>x</i>	<p>REAL for <code>sla_syamv</code></p> <p>DOUBLE PRECISION for <code>dla_syamv</code></p> <p>COMPLEX for <code>cla_syamv</code></p> <p>DOUBLE COMPLEX for <code>zla_syamv</code>.</p> <p>Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>X</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>.</p> <p>The value of <i>incx</i> must be non-zero.</p>
<i>beta</i>	<p>REAL for <code>sla_syamv</code> and <code>cla_syamv</code></p> <p>DOUBLE PRECISION for <code>dla_syamv</code> and <code>zla_syamv</code></p> <p>Specifies the scalar <i>beta</i>. When <i>beta</i> is zero, you do not need to set <i>y</i> on input.</p>
<i>y</i>	<p>REAL for <code>sla_syamv</code> and <code>cla_syamv</code></p> <p>DOUBLE PRECISION for <code>dla_syamv</code> and <code>zla_syamv</code></p> <p>Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with non-zero <i>beta</i>, the incremented array <i>y</i> must contain the vector <i>Y</i>.</p>
<i>incy</i>	<p>INTEGER. Specifies the increment for the elements of <i>y</i>.</p> <p>The value of <i>incy</i> must be non-zero.</p>

Output Parameters

<i>y</i>	Updated vector <i>Y</i> .
----------	---------------------------

?la_syrcond

Estimates the Skeel condition number for a symmetric indefinite matrix.

Syntax

```
call sla_syrcond( uplo, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
call dla_syrcond( uplo, n, a, lda, af, ldaf, ipiv, cmode, c, info, work, iwork )
```

Include Files

- mkl.fi

Description

The function estimates the Skeel condition number of

$op(A) * op2(C)$

where

the *cmode* parameter determines *op2* as follows:

<i>cmode</i> Value	op2(C)
1	<i>C</i>
0	<i>I</i>
-1	inv(<i>C</i>)

The Skeel condition number

$cond(A) = norminf(|inv(A)| |A|)$

is computed by computing scaling factors *R* such that

$diag(R) * A * op2(C)$

is row equilibrated and by computing the standard infinity-norm condition number.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i> , <i>af</i> , <i>c</i> , <i>work</i>	REAL for sla_syrcond DOUBLE PRECISION for dla_syrcond Arrays: <i>ab</i> (<i>lda</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix <i>A</i> . <i>af</i> (<i>ldaf</i> ,*) contains the The block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>L</i> or <i>U</i> as computed by ?sytrf.

The second dimension of a and af must be at least $\max(1, n)$.

c , DIMENSION n . The vector c in the formula $\text{op}(A) * \text{op2}(C)$.

$work$ is a workspace array of DIMENSION $(3*n)$.

lda INTEGER. The leading dimension of the array ab . $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of af . $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array with DIMENSION n . Details of the interchanges and the block structure of D as determined by `?sytrf`.

cmode INTEGER. Determines $\text{op2}(C)$ in the formula $\text{op}(A) * \text{op2}(C)$ as follows:

If $cmode = 1$, $\text{op2}(C) = C$.

If $cmode = 0$, $\text{op2}(C) = I$.

If $cmode = -1$, $\text{op2}(C) = \text{inv}(C)$.

iwork INTEGER. Workspace array with DIMENSION n .

Output Parameters

info INTEGER.

If $info = 0$, the execution is successful.

If $i > 0$, the i -th parameter is invalid.

Include Files

- `mk1.fi`

Description

The function computes the infinity norm condition number of

$\text{op}(A) * \text{inv}(\text{diag}(c))$

where the c is a REAL vector for `cla_syrcond_c` and a DOUBLE PRECISION vector for `zla_syrcond_c`.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.

Specifies the triangle of *A* to store:

If *uplo* = 'U', the upper triangle of *A* is stored,

If *uplo* = 'L', the lower triangle of *A* is stored.

n INTEGER. The number of linear equations, that is, the order of the matrix *A*; $n \geq 0$.

a COMPLEX for `cla_syrcond_c`
DOUBLE COMPLEX for `zla_syrcond_c`
Array, DIMENSION(*lda*, *). On entry, the *n*-by-*n* matrix *A*. The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

af COMPLEX for `cla_syrcond_c`
DOUBLE COMPLEX for `zla_syrcond_c`
Array, DIMENSION(*ldaf*, *). The block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* as computed by `?sytrf`. The second dimension of *af* must be at least $\max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*. $ldaf \geq \max(1, n)$.

ipiv INTEGER.
Array with DIMENSION *n*. Details of the interchanges and the block structure of *D* as determined by `?sytrf`.

c REAL for `cla_syrcond_c`
DOUBLE PRECISION for `zla_syrcond_c`
Array *c* with DIMENSION *n*. The vector *c* in the formula
$$\text{op}(A) * \text{inv}(\text{diag}(c)).$$

caply LOGICAL. If `.TRUE.`, then the function uses the vector *c* from the formula
$$\text{op}(A) * \text{inv}(\text{diag}(c)).$$

work COMPLEX for `cla_syrcond_c`
DOUBLE COMPLEX for `zla_syrcond_c`
Array DIMENSION $2*n$. Workspace.

rwork REAL for `cla_syrcond_c`
DOUBLE PRECISION for `zla_syrcond_c`
Array DIMENSION *n*. Workspace.

Output Parameters

info INTEGER.
If *info* = 0, the execution is successful.

If $i > 0$, the i -th parameter is invalid.

Description

The function computes the infinity norm condition number of

$op(A) * diag(x)$

where the x is a COMPLEX vector for `cla_syrcond_x` and a DOUBLE COMPLEX vector for `zla_syrcond_x`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of A to store: If <i>uplo</i> = 'U', the upper triangle of A is stored, If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The number of linear equations, that is, the order of the matrix A; $n \geq 0$.
<i>a</i>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array, DIMENSION(<i>lda</i> , *). On entry, the n -by- n matrix A. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.
<i>af</i>	COMPLEX for <code>cla_syrcond_c</code> DOUBLE COMPLEX for <code>zla_syrcond_c</code> Array, DIMENSION(<i>ldaf</i> , *). The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?sytrf</code> . The second dimension of <i>af</i> must be at least $\max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of the array <i>af</i> . $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER.

Array with `DIMENSIONn`. Details of the interchanges and the block structure of `D` as determined by `?sytrf`.

`x` `COMPLEX` for `cla_syrcond_c`
 `DOUBLE COMPLEX` for `zla_syrcond_c`
 Array `x` with `DIMENSIONn`. The vector `x` in the formula

$$\text{op}(A) * \text{inv}(\text{diag}(x)).$$

`work` `COMPLEX` for `cla_syrcond_c`
 `DOUBLE COMPLEX` for `zla_syrcond_c`
 Array `DIMENSION 2*n`. Workspace.

`rwork` `REAL` for `cla_syrcond_c`
 `DOUBLE PRECISION` for `zla_syrcond_c`
 Array `DIMENSIONn`. Workspace.

Output Parameters

`info` `INTEGER`.
 If `info = 0`, the execution is successful.
 If `i > 0`, the *i*-th parameter is invalid.

```

Include Files

- `mkl.fi`

Description

The `?la_syrfSX_extended` subroutine improves the computed solution to a system of linear equations by performing extra-precise iterative refinement and provides error bounds and backward error estimates for the solution. The `?syrfSX` routine calls `?la_syrfSX_extended` to perform iterative refinement.

In addition to normwise error bound, the code provides maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

Use `?la_syrfSX_extended` to set only the second fields of `err_bnds_norm` and `err_bnds_comp`.

Input Parameters

<code>prec_type</code>	<p>INTEGER.</p> <p>Specifies the intermediate precision to be used in refinement. The value is defined by <code>ilaprec(p)</code>, where <code>p</code> is a CHARACTER and:</p> <p>If <code>p = 'S'</code>: Single.</p> <p>If <code>p = 'D'</code>: Double.</p> <p>If <code>p = 'I'</code>: Indigenous.</p> <p>If <code>p = 'X', 'E'</code>: Extra.</p>
<code>uplo</code>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies the triangle of <i>A</i> to store:</p> <p>If <code>uplo = 'U'</code>, the upper triangle of <i>A</i> is stored,</p> <p>If <code>uplo = 'L'</code>, the lower triangle of <i>A</i> is stored.</p>
<code>n</code>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<code>nrhs</code>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrix <i>B</i>.</p>
<code>a, af, b, y</code>	<p>REAL for <code>sla_syrfSX_extended</code></p> <p>DOUBLE PRECISION for <code>dla_syrfSX_extended</code></p> <p>COMPLEX for <code>cla_syrfSX_extended</code></p> <p>DOUBLE COMPLEX for <code>zla_syrfSX_extended</code>.</p> <p>Arrays: <code>a(lda,*)</code>, <code>af(ldaf,*)</code>, <code>b(ldb,*)</code>, <code>y(ldy,*)</code>.</p> <p>The array <i>a</i> contains the original <i>n</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least <code>max(1,n)</code>.</p> <p>The array <i>af</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by <code>?sytrf</code>.</p> <p>The second dimension of <i>af</i> must be at least <code>max(1,n)</code>.</p> <p>The array <i>b</i> contains the right-hand-side of the matrix <i>B</i>. The second dimension of <i>b</i> must be at least <code>max(1,nrhs)</code>.</p>

The array *y* on entry contains the solution matrix *X* as computed by ?sytrs. The second dimension of *y* must be at least $\max(1, nrhs)$.

lda INTEGER. The leading dimension of the array *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The leading dimension of the array *af*; $ldaf \geq \max(1, n)$.

ipiv INTEGER.

Array with DIMENSION *n*. Details of the interchanges and the block structure of *D* as determined by ?sytrf.

colequ LOGICAL. If *colequ* = .TRUE., column equilibration was done to *A* before calling this routine. This is needed to compute the solution and error bounds correctly.

c REAL for sla_syrfssx_extended and cla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended and
zla_syrfssx_extended.

c contains the column scale factors for *A*. If *colequ* = .FALSE., *c* is not used.

If *c* is input, each element of *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by power of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The leading dimension of the array *b*; $ldb \geq \max(1, n)$.

ldy INTEGER. The leading dimension of the array *y*; $ldy \geq \max(1, n)$.

n_norms INTEGER. Determines which error bounds to return. See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

If *n_norms* ≥ 1 , returns normwise error bounds.

If *n_norms* ≥ 2 , returns componentwise error bounds.

err_bnds_norm REAL for sla_syrfssx_extended and cla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended and
zla_syrfssx_extended.

Array, DIMENSION(*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error.

Normwise relative error in the *i*-th solution vector is defined as follows:

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i,:)` corresponds to the i -th right-hand side.

The second index in `err_bnds_norm(:,err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_syrfsx_extended/cla_syrfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_syrfsx_extended/zla_syrfsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_syrfsx_extended/cla_syrfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_syrfsx_extended/zla_syrfsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for <code>sla_syrfsx_extended/cla_syrfsx_extended</code> and $\sqrt{n} * \text{dlamch}(\epsilon)$ for <code>dla_syrfsx_extended/zla_syrfsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1. Use this subroutine to set only the second field above.

`err_bnds_comp`

REAL for `sla_syrfsx_extended` and `cla_syrfsx_extended`
DOUBLE PRECISION for `dla_syrfsx_extended` and `zla_syrfsx_extended`.

Array, `DIMENSION(nrhs, n_err_bnds)`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params(3) = 0.0`), then `err_bnds_comp` is not accessed. If `n_err_bnds < 3`, then at most the first `(:, n_err_bnds)` entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

<code>err=1</code>	"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_syrrsx_extended/cla_syrrsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_syrrsx_extended/zla_syrrsx_extended</code> .
<code>err=2</code>	"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_syrrsx_extended/cla_syrrsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_syrrsx_extended/zla_syrrsx_extended</code> . This error bound should only be trusted if the previous boolean is true.
<code>err=3</code>	Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold <code>sqrt(n)*slamch(ε)</code> for <code>sla_syrrsx_extended/cla_syrrsx_extended</code> and <code>sqrt(n)*dlamch(ε)</code> for <code>dla_syrrsx_extended/zla_syrrsx_extended</code> to determine if the error estimate is "guaranteed". These reciprocal

condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix Z .

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

Use this subroutine to set only the second field above.

res, *dy*, *y_tail*

REAL for sla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended
COMPLEX for cla_syrfssx_extended
DOUBLE COMPLEX for zla_syrfssx_extended.

Workspace arrays of DIMENSION n .

res holds the intermediate residual.

dy holds the intermediate solution.

y_tail holds the trailing bits of the intermediate solution.

ayb

REAL for sla_syrfssx_extended and cla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended and
zla_syrfssx_extended.

Workspace array, DIMENSION n .

rcond

REAL for sla_syrfssx_extended and cla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended and
zla_syrfssx_extended.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

ithresh

INTEGER. The maximum number of residual computations allowed for refinement. The default is 10. For 'aggressive', set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

rthresh

REAL for sla_syrfssx_extended and cla_syrfssx_extended
DOUBLE PRECISION for dla_syrfssx_extended and
zla_syrfssx_extended.

Determines when to stop refinement if the error estimate stops decreasing. Refinement stops when the next solution no longer satisfies

$\text{norm}(\text{dx}_{\{i+1\}}) < \text{rthresh} * \text{norm}(\text{dx}_i)$

where $\text{norm}(z)$ is the infinity norm of Z .

rthresh satisfies

$0 < rthresh \leq 1$.

The default value is 0.5. For 'aggressive' set to 0.9 to permit convergence on extremely ill-conditioned matrices.

dz_ub

REAL for *sla_syrfSX_extended* and *cla_syrfSX_extended*

DOUBLE PRECISION for *dla_syrfSX_extended* and
zla_syrfSX_extended.

Determines when to start considering componentwise convergence. Componentwise *dz_ub* convergence is only considered after each component of the solution y is stable, that is, the relative change in each component is less than *dz_ub*. The default value is 0.25, requiring the first bit to be stable.

ignore_cwise

LOGICAL

If **.TRUE.**, the function ignores componentwise convergence. Default value is **.FALSE.**

Output Parameters

y

REAL for *sla_syrfSX_extended*

DOUBLE PRECISION for *dla_syrfSX_extended*

COMPLEX for *cla_syrfSX_extended*

DOUBLE COMPLEX for *zla_syrfSX_extended*.

The improved solution matrix Y .

berr_out

REAL for *sla_syrfSX_extended* and *cla_syrfSX_extended*

DOUBLE PRECISION for *dla_syrfSX_extended* and
zla_syrfSX_extended.

Array, DIMENSION *nrhs*. *berr_out(j)* contains the componentwise relative backward error for right-hand-side j from the formula

$$\max(i) \left(\text{abs}(\text{res}(i)) / \left(\text{abs}(\text{op}(A)) * \text{abs}(y) + \text{abs}(B) \right) (i) \right)$$

where $\text{abs}(z)$ is the componentwise absolute value of the matrix or vector Z . This is computed by *?la_lin_berr*.

err_bnds_norm,
err_bnds_comp

Values of the corresponding input parameters improved after iterative refinement and stored in the second column of the array (*1:nrhs*, 2). The other elements are kept unchanged.

info

INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = $-i$, the i -th parameter had an illegal value.

?la_syrpvgrw

Computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$ for a symmetric indefinite matrix.

Syntax

```
call sla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call dla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call cla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
call zla_syrpvgrw( uplo, n, info, a, lda, af, ldaf, ipiv, work )
```

Include Files

- mkl.fi

Description

The ?la_syrpvgrw routine computes the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the *LU* factorization of the equilibrated matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies the triangle of <i>A</i> to store: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored, If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>info</i>	INTEGER. The value of INFO returned from ?sytrf, that is, the pivot in column <i>info</i> is exactly 0.
<i>a, af</i>	REAL for sla_syrpvgrw DOUBLE PRECISION for dla_syrpvgrw COMPLEX for cla_syrpvgrw DOUBLE COMPLEX for zla_syrpvgrw. Arrays: <i>a</i> (<i>lda</i> ,*), <i>af</i> (<i>ldaf</i> ,*). The array <i>a</i> contains the input <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.

The array *af* contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* as computed by ?sytrf.

The second dimension of *af* must be at least $\max(1, n)$.

<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION <i>n</i> . Details of the interchanges and the block structure of <i>D</i> as determined by ?sytrf.
<i>work</i>	REAL for sla_syrpvgrw and cla_syrpvgrw DOUBLE PRECISION for dla_syrpvgrw and zla_syrpvgrw. Workspace array, dimension $2*n$.

See Also

[?sytrf](#)

[?la_wwaddw](#)

Adds a vector into a doubled-single vector.

Syntax

```
call sla_wwaddw( n, x, y, w )
call dla_wwaddw( n, x, y, w )
call cla_wwaddw( n, x, y, w )
call zla_wwaddw( n, x, y, w )
```

Include Files

- mkl.fi

Description

The ?la_wwaddw routine adds a vector *W* into a doubled-single vector (*X*, *Y*). This works for all existing IBM hex and binary floating-point arithmetics, but not for decimal.

Input Parameters

<i>n</i>	INTEGER. The length of vectors <i>X</i> , <i>Y</i> , and <i>W</i> .
<i>x</i> , <i>y</i> , <i>w</i>	REAL for sla_wwaddw DOUBLE PRECISION for dla_wwaddw COMPLEX for cla_wwaddw DOUBLE COMPLEX for zla_wwaddw. Arrays DIMENSION <i>n</i> . <i>x</i> and <i>y</i> contain the first and second parts of the doubled-single accumulation vector, respectively.

w contains the vector W to be added.

Output Parameters

x, y Contain the first and second parts of the doubled-single accumulation vector, respectively, after adding the vector W .

mkl_?tppack

Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.

Syntax

```
call mkl_stppack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_dtpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_ctppack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_ztpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_tppack (ap, i, j, rows, cols, a[, uplo] [, trans] [, info])
```

Include Files

- mkl.fi, lapack.f90

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard full format to packed format

$$AP_{i:i+rows-1, j:j+cols-1} := op(A)$$

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of the matrix AP are skipped.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the matrix <i>AP</i> is upper or lower triangular.</p> <p>If <i>uplo</i> = 'U', <i>AP</i> is upper triangular.</p> <p>If <i>uplo</i> = 'L': <i>AP</i> is lower triangular.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies whether or not the copied block of <i>A</i> is transposed or not.</p> <p>If <i>trans</i> = 'N', no transpose: $\text{op}(A) = A$.</p> <p>If <i>trans</i> = 'T', transpose: $\text{op}(A) = A^T$.</p> <p>If <i>trans</i> = 'C', conjugate transpose: $\text{op}(A) = A^H$. For real data this is the same as <i>trans</i> = 'T'.</p>
<i>n</i>	INTEGER. The order of the matrix <i>AP</i> ; $n \geq 0$
<i>i, j</i>	<p>INTEGER. Coordinates of the left upper corner of the destination submatrix in <i>AP</i>.</p> <p>If <i>uplo</i>='U', $1 \leq i \leq j \leq n$.</p> <p>If <i>uplo</i>='L', $1 \leq j \leq i \leq n$.</p>
<i>rows</i>	INTEGER. Number of rows in the destination submatrix. $0 \leq \text{rows} \leq n - i + 1$.
<i>cols</i>	INTEGER. Number of columns in the destination submatrix. $0 \leq \text{cols} \leq n - j + 1$.
<i>a</i>	<p>REAL for mkl_stppack</p> <p>DOUBLE PRECISION for mkl_dtpack</p> <p>COMPLEX for mkl_ctppack</p> <p>DOUBLE COMPLEX for mkl_ztpack</p> <p>Pointer to the source submatrix.</p> <p>Array <i>a</i>(<i>lda</i>, *) contains the <i>rows</i>-by-<i>cols</i> submatrix stored as unpacked rows-by-columns if <i>trans</i> = 'N', or unpacked columns-by-rows if <i>trans</i> = 'T' or <i>trans</i> = 'C'. The size of <i>a</i> must be at least <i>lda</i>*<i>cols</i> for <i>trans</i> = 'N' or <i>lda</i>*<i>rows</i> for <i>trans</i>='T' or <i>trans</i>='C'.</p>

NOTE

If there are elements outside of the triangular part of *AP*, they are skipped and are not copied from *a*.

Output Parameters

<i>ap</i>	<p>REAL for mkl_stppack</p> <p>DOUBLE PRECISION for mkl_dtpack</p>
-----------	--

COMPLEX for `mkl_ctppack`

DOUBLE COMPLEX for `mkl_ztppack`

Array of size at least $\max(1, n(n+1)/2)$. The array `ap` contains either the upper or the lower triangular part of the matrix AP (as specified by `uplo`) in packed storage (see [Matrix Storage Schemes](#)). The submatrix of `ap` from row i to row $i + rows - 1$ and column j to column $j + cols - 1$ is overwritten with a copy of the source matrix.

`info`

INTEGER. If `info=0`, the execution is successful. If `info = -i`, the i -th parameter had an illegal value.

mkl_?tpunpack

Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.

Syntax

```
call mkl_stpunpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_dtpunpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_ctpunpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_ztpunpack (uplo, trans, n, ap, i, j, rows, cols, a, lda, info )
call mkl_tpunpack (ap, i, j, rows, cols, a[, uplo] [, trans] [, info])
```

Include Files

- `mkl.fi`, `lapack.f90`

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard packed format to full format.

$A := op(AP_{i:i+rows-1, j:j+cols-1})$

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of AP are skipped.

Input Parameters

The data types are given for the Fortran interface.

<i>uplo</i>	<p>CHARACTER*1. Specifies whether matrix <i>AP</i> is upper or lower triangular.</p> <p>If <i>uplo</i> = 'U', <i>AP</i> is upper triangular.</p> <p>If <i>uplo</i> = 'L': <i>AP</i> is lower triangular.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies whether or not the copied block of <i>AP</i> is transposed.</p> <p>If <i>trans</i> = 'N', no transpose: $\text{op}(AP) = AP$.</p> <p>If <i>trans</i> = 'T', transpose: $\text{op}(AP) = AP^T$.</p> <p>If <i>trans</i> = 'C', conjugate transpose: $\text{op}(AP) = AP^H$. For real data this is the same as <i>trans</i> = 'T'.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>AP</i>; $n \geq 0$.</p>
<i>ap</i>	<p>REAL for mkl_stpunpack</p> <p>DOUBLE PRECISION for mkl_dtpunpack</p> <p>COMPLEX for mkl_ctpunpack</p> <p>DOUBLE COMPLEX for mkl_ztpunpack</p> <p>Array, size at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains either the upper or the lower triangular part of the matrix <i>AP</i> (as specified by <i>uplo</i>) in packed storage (see Matrix Storage Schemes). It is the source for the submatrix of <i>AP</i> from row <i>i</i> to row <i>i</i> + <i>rows</i> - 1 and column <i>j</i> to column <i>j</i> + <i>cols</i> - 1 to be copied.</p>
<i>i, j</i>	<p>INTEGER. Coordinates of left upper corner of the submatrix in <i>AP</i> to copy.</p> <p>If <i>uplo</i>='U', $1 \leq i \leq j \leq n$.</p> <p>If <i>uplo</i>='L', $1 \leq j \leq i \leq n$.</p>
<i>rows</i>	<p>INTEGER. Number of rows to copy. $0 \leq \text{rows} \leq n - i + 1$.</p>
<i>cols</i>	<p>INTEGER. Number of columns to copy. $0 \leq \text{cols} \leq n - j + 1$.</p>
<i>lda</i>	<p>INTEGER. The leading dimension of array <i>a</i>.</p> <p>$lda \geq \max(1, \text{rows})$ for <i>trans</i> = 'N' and $lda \geq \max(1, \text{cols})$ for <i>trans</i>='T' or <i>trans</i>='C'.</p>

Output Parameters

<i>a</i>	<p>REAL for mkl_stpunpack</p> <p>DOUBLE PRECISION for mkl_dtpunpack</p> <p>COMPLEX for mkl_ctpunpack</p> <p>DOUBLE COMPLEX for mkl_ztpunpack</p>
----------	--

Pointer to the destination matrix. The size of a must be at least $lda*cols$ for $trans = 'N'$ or $lda*rows$ for $trans='T'$ or $trans='C'$. On exit, array a is overwritten with a copy of the unpacked *rows-by-cols* submatrix of ap unpacked rows-by-columns if $trans = 'N'$, or unpacked columns-by-rows if $trans = 'T'$ or $trans = 'C'$.

NOTE

If there are elements outside of the triangular part of ap indicated by $uplo$, they are skipped and are not copied to a .

info

INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Utility Functions and Routines

This section describes LAPACK utility functions and routines.

Summary information about these routines is given in the following table:

LAPACK Utility Routines

Routine Name	Data Types	Description
<code>ilaver</code>		Returns the version of the Lapack library.
<code>ilaenv</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>iparmq</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>ieeeck</code>		Checks if the infinity and NaN arithmetic is safe. Called by <code>ilaenv</code> .
<code>?labad</code>	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<code>?lamch</code>	s, d	Determines machine parameters for floating-point arithmetic.
<code>?lamc1</code>	s, d	Called from <code>?lamc2</code> . Determines machine parameters given by <i>beta</i> , <i>t</i> , <i>rnd</i> , <i>ieee1</i> .
<code>?lamc2</code>	s, d	Used by <code>?lamch</code> . Determines machine parameters specified in its arguments list.
<code>?lamc3</code>	s, d	Called from <code>?lamc1</code> - <code>?lamc5</code> . Intended to force <i>a</i> and <i>b</i> to be stored prior to doing the addition of <i>a</i> and <i>b</i> .
<code>?lamc4</code>	s, d	This is a service routine for <code>?lamc2</code> .
<code>?lamc5</code>	s, d	Called from <code>?lamc2</code> . Attempts to compute the largest machine floating-point number, without overflow.
<code>chla_transtype</code>		Translates a BLAST-specified integer constant to the character string specifying a transposition operation.
<code>iladiag</code>		Translates a character string specifying whether a matrix has a unit diagonal or not to the relevant BLAST-specified integer constant.

Routine Name	Data Types	Description
<code>ilaprec</code>		Translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.
<code>ilatrans</code>		Translates a character string specifying a transposition operation to the BLAST-specified integer constant.
<code>ilauplo</code>		Translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.
<code>xerbla_array</code>		Assists other languages in calling the <code>xerbla</code> function.

See Also

[lsame](#) Tests two characters for equality regardless of the case.

[lsamen](#) Tests two character strings for equality regardless of the case.

[second/dsecnd](#) Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

[xerbla](#) Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

ilaver

Returns the version of the LAPACK library.

Syntax

```
call ilaver( vers_major, vers_minor, vers_patch )
```

Include Files

- `mkl.fi`

Description

This routine returns the version of the LAPACK library.

Output Parameters

<code>vers_major</code>	INTEGER. Returns the major version of the LAPACK library.
<code>vers_minor</code>	INTEGER. Returns the minor version from the major version of the LAPACK library.
<code>vers_patch</code>	INTEGER. Returns the patch version from the minor version of the LAPACK library.

ilaenv

Environmental enquiry function that returns values for tuning algorithmic performance.

Syntax

```
value = ilaenv( ispec, name, opts, n1, n2, n3, n4 )
```

Include Files

- `mk1.fi`

Description

The enquiry function `ilaenv` is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* below for a description of the parameters.

This version provides a set of parameters that should give good, but not optimal, performance on many of the currently available computers.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

ispec

INTEGER.

Specifies the parameter to be returned as the value of `ilaenv`:

= 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance.

= 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.

= 3: the crossover point (in a block routine, for n less than this value, an unblocked routine should be used)

= 4: the number of shifts, used in the nonsymmetric eigenvalue routines (deprecated)

= 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k -by- m , where k is given by `ilaenv(2,...)` and m by `ilaenv(5,...)`

= 6: the crossover point for the SVD (when reducing an m -by- n matrix to bidiagonal form, if $\max(m,n)/\min(m,n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.)

= 7: the number of processors

= 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems (deprecated).

= 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?gelzd` and `?gesdd`)

=10: ieee NaN arithmetic can be trusted not to trap

=11: infinity arithmetic can be trusted not to trap

12 $\leq ispec \leq$ 16: ?hseqr or one of its subroutines, see iparmq for detailed explanation.

name CHARACTER*(*) . The name of the calling subroutine, in either upper case or lower case.

opts CHARACTER*(*) . The character options to the subroutine *name*, concatenated into a single character string. For example, *uplo* = 'U', *trans* = 'T', and *diag* = 'N' for a triangular routine would be specified as *opts* = 'UTN'.

n1, n2, n3, n4 INTEGER. Problem dimensions for the subroutine *name*; these may not all be required.

Output Parameters

value INTEGER.

If *value* \geq 0: the value of the parameter specified by *ispec*;

If *value* = -k < 0: the k-th argument had an illegal value.

Application Notes

The following conventions have been used when calling *ilaenv* from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1, n2, n3, n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by *ilaenv* is checked for validity in the calling subroutine. For example, *ilaenv* is used to retrieve the optimal blocksize for *strtri* as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
```

```
if( nb.le.1 ) nb = max( 1, n )
```

See Also

[?hseqr](#)

[iparmq](#)

iparmq

Environmental enquiry function which returns values for tuning algorithmic performance.

Syntax

```
value = iparmq( ispec, name, opts, n, ilo, ihi, lwork )
```

Include Files

- `mkl.fi`

Description

The function sets problem and machine dependent parameters useful for ?hseqr and its subroutines. It is called whenever `ilaenv` is called with $12 \leq ispec \leq 16$.

Input Parameters

<i>ispec</i>	<p>INTEGER.</p> <p>Specifies the parameter to be returned as the value of <code>iparmq</code>:</p> <p>= 12: (<i>inmin</i>) Matrices of order <i>nmin</i> or less are sent directly to ?lahqr, the implicit double shift QR algorithm. <i>nmin</i> must be at least 11.</p> <p>= 13: (<i>inwin</i>) Size of the deflation window. This is best set greater than or equal to the number of simultaneous shifts <i>ns</i>. Larger matrices benefit from larger deflation windows.</p> <p>= 14: (<i>inibl</i>) Determines when to stop nibbling and invest in an (expensive) multi-shift QR sweep. If the aggressive early deflation subroutine finds <i>ld</i> converged eigenvalues from an order <i>nw</i> deflation window and $ld > (nw * nibble) / 100$, then the next QR sweep is skipped and early deflation is applied immediately to the remaining active diagonal block. Setting <code>iparmq(ispec=14)=0</code> causes TTQRE to skip a multi-shift QR sweep whenever early deflation finds a converged eigenvalue. Setting <code>iparmq(ispec=14)</code> greater than or equal to 100 prevents TTQRE from skipping a multi-shift QR sweep.</p> <p>= 15: (<i>nshfts</i>) The number of simultaneous shifts in a multi-shift QR iteration.</p> <p>= 16: (<i>iacc22</i>) <code>iparmq</code> is set to 0, 1 or 2 with the following meanings.</p> <p>0: During the multi-shift QR sweep, ?laqr5 does not accumulate reflections and does not use matrix-matrix multiply to update the far-from-diagonal matrix entries.</p> <p>1: During the multi-shift QR sweep, ?laqr5 and/or ?laqr3 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.</p> <p>2: During the multi-shift QR sweep, ?laqr5 accumulates reflections and takes advantage of 2-by-2 block structure during matrix-matrix multiplies.</p> <p>(If ?trrm is slower than ?gemm, then <code>iparmq(ispec=16)=1</code> may be more efficient than <code>iparmq(ispec=16)=2</code> despite the greater level of arithmetic work implied by the latter choice.)</p>
<i>name</i>	CHARACTER*(*) . The name of the calling subroutine.
<i>opts</i>	CHARACTER*(*) . This is a concatenation of the string arguments to TTQRE.
<i>n</i>	INTEGER. <i>n</i> is the order of the Hessenberg matrix <i>H</i> .
<i>ilo, ihi</i>	<p>INTEGER.</p> <p>It is assumed that <i>H</i> is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$.</p>
<i>lwork</i>	INTEGER.

The amount of workspace available.

Output Parameters

value INTEGER.
 If *value* ≥ 0 : the value of the parameter specified by *iparmq*;
 If *value* = $-k < 0$: the *k*-th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, *n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal blocksize for `strtri` as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
```

```
if( nb.le.1 ) nb = max( 1, n )
```

ieeeck

*Checks if the infinity and NaN arithmetic is safe.
 Called by ilaenv.*

Syntax

```
ival = ieeck( ispec, zero, one )
```

Include Files

- `mkl.fi`

Description

The function `ieeeck` is called from `ilaenv` to verify that infinity and possibly NaN arithmetic is safe, that is, will not trap.

Input Parameters

ispec INTEGER.
 Specifies whether to test just for infinity arithmetic or both for infinity and NaN arithmetic:
 If *ispec* = 0: Verify infinity arithmetic only.
 If *ispec* = 1: Verify infinity and NaN arithmetic.

zero REAL. Must contain the value 0.0
 This is passed to prevent the compiler from optimizing away this code.

one REAL. Must contain the value 1.0
This is passed to prevent the compiler from optimizing away this code.

Output Parameters

ival INTEGER.
If *ival* = 0: Arithmetic failed to produce the correct answers.
If *ival* = 1: Arithmetic produced the correct answers.

?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call slabad( small, large )
call dlabad( small, large )
```

Include Files

- mkl.fi

Description

The routine takes as input the values computed by `slamch/dlamch` for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `?lamch`. This subroutine is needed because `?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Input Parameters

small REAL for slabad
DOUBLE PRECISION for dlabad.
The underflow threshold as computed by `?lamch`.

large REAL for slabad
DOUBLE PRECISION for dlabad.
The overflow threshold as computed by `?lamch`.

Output Parameters

small On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of *small*, otherwise unchanged.

large On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of *large*, otherwise unchanged.

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = slamch( cmach )
```

```
val = dlamch( cmach )
```

Include Files

- mkl.fi

Description

The function ?lamch determines single precision and double precision machine parameters.

Input Parameters

cmach CHARACTER*1. Specifies the value to be returned by ?lamch:

- = 'E' or 'e', *val* = *eps*
- = 'S' or 's', *val* = *sfmin*
- = 'B' or 'b', *val* = *base*
- = 'P' or 'p', *val* = *eps***base*
- = 'n' or 'n', *val* = *t*
- = 'R' or 'r', *val* = *rnd*
- = 'M' or 'm', *val* = *emin*
- = 'U' or 'u', *val* = *rmin*
- = 'L' or 'l', *val* = *emax*
- = 'O' or 'o', *val* = *rmax*

where

- eps* = relative machine precision;
- sfmin* = safe minimum, such that 1/*sfmin* does not overflow;
- base* = base of the machine;
- prec* = *eps***base*;
- t* = number of (base) digits in the mantissa;
- rnd* = 1.0 when rounding occurs in addition, 0.0 otherwise;
- emin* = minimum exponent before (gradual) underflow;
- rmin* = *underflow_threshold* - *base***(*emin*-1);
- emax* = largest exponent before overflow;
- rmax* = *overflow_threshold* - (*base****emax*)*(1-*eps*).

NOTE

You can use a character string for *cmach* instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, 'Precision' is interpreted as 'p'.

Output Parameters

val REAL for slamch
DOUBLE PRECISION for dlamch
Value returned by the function.

?lamc1

Called from ?lamc2. Determines machine parameters given by beta, t, rnd, ieee1.

Syntax

```
call slamc1( beta, t, rnd, ieee1 )
call dlamc1( beta, t, rnd, ieee1 )
```

Include Files

- mkl.fi

Description

The routine ?lamc1 determines machine parameters given by *beta*, *t*, *rnd*, *ieee1*.

Output Parameters

beta INTEGER. The base of the machine.

t INTEGER. The number of (*beta*) digits in the mantissa.

rnd LOGICAL.
Specifies whether proper rounding (*rnd* = .TRUE.) or chopping (*rnd* = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.

ieee1 LOGICAL.
Specifies whether rounding appears to be done in the *ieee* 'round to nearest' style.

?lamc2

Used by ?lamch. Determines machine parameters specified in its arguments list.

Syntax

```
call slamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
call dlamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
```

Include Files

- mkl.fi

Description

The routine ?lamc2 determines machine parameters specified in its arguments list.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>eps</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest positive number such that $fl(1.0 - eps) < 1.0$, where <i>fl</i> denotes the computed value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow occurs.
<i>rmin</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest normalized number for the machine, given by $base^{emin-1}$, where <i>base</i> is the floating point value of <i>beta</i> .
<i>emax</i>	INTEGER. The maximum exponent before overflow occurs.
<i>rmax</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The largest positive number for the machine, given by $base^{emax(1 - eps)}$, where <i>base</i> is the floating point value of <i>beta</i> .

?lamc3

Called from ?lamc1-?lamc5. Intended to force a and b to be stored prior to doing the addition of a and b.

Syntax

```
val = slamc3( a, b )
```

```
val = dlamc3( a, b )
```

Include Files

- mkl.fi

Description

The routine is intended to force A and B to be stored prior to doing the addition of A and B , for use in situations where optimizers might hold one of these in a register.

Input Parameters

a, b REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The values a and b .

Output Parameters

val REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The result of adding values a and b .

?lamc4

This is a service routine for ?lamc2.

Syntax

```
call slamc4( emin, start, base )
```

```
call dlamc4( emin, start, base )
```

Include Files

- mkl.fi

Description

This is a service routine for [?lamc2](#).

Input Parameters

$start$ REAL for slamc4
 DOUBLE PRECISION for dlamc4
 The starting point for determining $emin$.

$base$ INTEGER. The base of the machine.

Output Parameters

emin INTEGER. The minimum exponent before (gradual) underflow, computed by setting $a = start$ and dividing by $base$ until the previous a can not be recovered.

?lamc5

Called from ?lamc2. Attempts to compute the largest machine floating-point number, without overflow.

Syntax

```
call slamc5( beta, p, emin, ieee, emax, rmax)
call dlamc5( beta, p, emin, ieee, emax, rmax)
```

Include Files

- mkl.fi

Description

The routine ?lamc5 attempts to compute $rmax$, the largest machine floating-point number, without overflow. It assumes that $emax + abs(emin)$ sum approximately to a power of 2. It will fail on machines where this assumption does not hold, for example, the Cyber 205 ($emin = -28625$, $emax = 28718$). It will also fail if the value supplied for $emin$ is too large (that is, too close to zero), probably with overflow.

Input Parameters

beta INTEGER. The base of floating-point arithmetic.

p INTEGER. The number of base $beta$ digits in the mantissa of a floating-point value.

emin INTEGER. The minimum exponent before (gradual) underflow.

ieee LOGICAL. A logical flag specifying whether or not the arithmetic system is thought to comply with the IEEE standard.

Output Parameters

emax INTEGER. The largest exponent before overflow.

rmax REAL for slamc5
DOUBLE PRECISION for dlamc5
The largest machine floating-point number.

chla_transtype

Translates a BLAST-specified integer constant to the character string specifying a transposition operation.

Syntax

```
val = chla_transtype( trans )
```

Output Parameters

<i>val</i>	INTEGER
	Value returned by the function.

ilaprec

Translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.

Syntax

```
val = ilaprec( prec )
```

Include Files

- mkl.fi

Description

The `ilaprec` function translates a character string specifying an intermediate precision to the relevant BLAST-specified integer constant.

The function returns an `INTEGER`. If `val < 0`, the input is not a character indicating a supported intermediate precision. Otherwise, the function returns the constant value corresponding to `prec`.

Input Parameters

<i>prec</i>	CHARACTER*1.
	Specifies the form of the system of equations:
	If <code>prec = 'S'</code> : Single.
	If <code>prec = 'D'</code> : Double.
	If <code>prec = 'I'</code> : Indigenous.
	If <code>prec = 'X', 'E'</code> : Extra.

Output Parameters

<i>val</i>	INTEGER
	Value returned by the function.

ilatrans

Translates a character string specifying a transposition operation to the BLAST-specified integer constant.

Syntax

```
val = ilatrans( trans )
```

Include Files

- mkl.fi

Description

The `ilatrans` function translates a character string specifying a transposition operation to the BLAST-specified integer constant.

The function returns a `INTEGER`. If `val < 0`, the input is not a character indicating a transposition operator. Otherwise, the function returns the constant value corresponding to `trans`.

Input Parameters

<code>trans</code>	<p>CHARACTER*1.</p> <p>Specifies the form of the system of equations:</p> <p>If <code>trans = 'N'</code>: No transpose.</p> <p>If <code>trans = 'T'</code>: Transpose.</p> <p>If <code>trans = 'C'</code>: Conjugate Transpose.</p>
--------------------	---

Output Parameters

<code>val</code>	<p>INTEGER</p> <p>Character that specifies a transposition operation.</p>
------------------	---

ilauplo

Translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.

Syntax

```
val = ilauplo( uplo )
```

Include Files

- `mkl.fi`

Description

The `ilauplo` function translates a character string specifying an upper- or lower-triangular matrix to the relevant BLAST-specified integer constant.

The function returns an `INTEGER`. If `val < 0`, the input is not a character indicating an upper- or lower-triangular matrix. Otherwise, the function returns the constant value corresponding to `uplo`.

Input Parameters

<code>diag</code>	<p>CHARACTER.</p> <p>Specifies the form of the system of equations:</p> <p>If <code>diag = 'U'</code>: <i>A</i> is upper triangular.</p> <p>If <code>diag = 'L'</code>: <i>A</i> is lower triangular.</p>
-------------------	---

Output Parameters

<code>val</code>	<p>INTEGER</p>
------------------	----------------

Value returned by the function.

xerbla_array

Assists other languages in calling the xerbla function.

Syntax

```
call xerbla_array( sname_array, sname_len, info )
```

Include Files

- mkl.fi

Description

The routine assists other languages in calling the error handling `xerbla` function. Rather than taking a Fortran string argument as the function name, `xerbla_array` takes an array of single characters along with the array length. The routine then copies up to 32 characters of that array into a Fortran string and passes that to `xerbla`. If called with a non-positive `sname_len`, the routine will call `xerbla` with a string of all blank characters.

If some macro or other device makes `xerbla_array` available to C99 by a name `lapack_xerbla` and with a common Fortran calling convention, a C99 program could invoke `xerbla` via:

```
{
  int flen = strlen(__func__);
  lapack_xerbla(__func__, &flen, &info);
}
```

Providing `xerbla_array` is not necessary for intercepting LAPACK errors. `xerbla_array` calls `xerbla`.

Output Parameters

<code>sname_array</code>	CHARACTER(1).
	Array, dimension (<code>sname_len</code>). The name of the routine that called <code>xerbla_array</code> .
<code>sname_len</code>	INTEGER.
	The length of the name in <code>sname_array</code> .
<code>info</code>	INTEGER.
	Position of the invalid parameter in the parameter list of the calling routine.

Test Functions and Routines

This section describes LAPACK test functions and routines.

Summary information about these routines is given in the following table:

LAPACK Test Routines

Routine Name	Data Types	Description
<code>?lagge</code>	s, d, c, z	Generates a general m -by- n matrix .

Routine Name	Data Types	Description
<code>?laghe</code>	<code>c, z</code>	Generates a complex Hermitian matrix .
<code>?lagsy</code>	<code>s, d, c, z</code>	Generates a symmetric matrix by pre- and post- multiplying a real diagonal matrix with a random unitary matrix .
<code>?latms</code>	<code>s, d, c, z</code>	Generates a general m -by- n matrix with specific singular values.

`?latms`

Generates a general m -by- n matrix with specific singular values.

Syntax

```
call slatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
```

```
call dlatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
```

```
call clatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
```

```
call zlatms (m, n, dist, iseed, sym, d, mode, cond, dmax, kl, ku, pack, a, lda, work, info)
```

Description

The `?latms` routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to d , where d is input or computed according to `mode`, `cond`, `dmax`, and `sym` as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:

Method A

1. Generate a dense m -by- n matrix by multiplying d on the left and the right by random unitary matrices, then:
2. Reduce the bandwidth according to `kl` and `ku`, using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to m and n) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and `lda` is at least m (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than $(1/2)*n$ for symmetric or Hermitian or less than $.3*n+m$ for nonsymmetric), or `lda` is less than m and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the `pack` parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

Input Parameters

The data types are given for the Fortran interface.

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ($n \geq 0$).
<i>dist</i>	<p>CHARACTER*1. Specifies the type of distribution to be used to generate the random singular values or eigenvalues:</p> <ul style="list-style-type: none"> • 'U': uniform distribution (0, 1) • 'S': symmetric uniform distribution (-1, 1) • 'N': normal distribution (0, 1)
<i>iseed</i>	<p>INTEGER. Array with size 4.</p> <p>Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and <i>iseed</i>(4) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to ?latms to continue the same random number sequence.</p>
<i>sym</i>	<p>CHARACTER*1.</p> <p>If <i>sym</i>='S' or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>; they can be positive, negative, or zero.</p> <p>If <i>sym</i>='P', the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>.</p> <p>If <i>sym</i>='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>.</p>
<i>d</i>	<p>REAL for slatms and clatms</p> <p>DOUBLE PRECISION for dlatms and zlatms</p> <p>Array, size (MIN(<i>m</i>, <i>n</i>))</p> <p>This array is used to specify the singular values or eigenvalues of <i>A</i> (see the description of <i>sym</i>). If <i>mode</i>=0, then <i>d</i> is assumed to contain the eigenvalues or singular values, otherwise elements of <i>d</i> are computed according to <i>mode</i>, <i>cond</i>, and <i>dmax</i>.</p>
<i>mode</i>	<p>INTEGER. Describes how the singular/eigenvalues are specified.</p> <ul style="list-style-type: none"> • <i>mode</i> = 0: use <i>d</i> as input • <i>mode</i> = 1: set $d(1) = 1$ and $d(2:n) = 1.0/cond$ • <i>mode</i> = 2: set $d(1:n-1) = 1$ and $d(n) = 1.0/cond$ • <i>mode</i> = 3: set $d(i) = cond^{-(i-1)/(n-1)}$ • <i>mode</i> = 4: set $d(i) = 1 - (i-1)/(n-1) * (1 - 1/cond)$

- *mode* = 5: set elements of *d* to random numbers in the range $(1/\text{cond}, 1)$ such that their logarithms are uniformly distributed.
- *mode* = 6: set elements of *d* to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as $\text{ABS}(\text{mode})$, except that the order of the elements of *d* is reversed. Thus, if *mode* is positive, *d* has entries ranging from 1 to $1/\text{cond}$, if negative, from $1/\text{cond}$ to 1.

If *sym*='S' or 'H', and *mode* is not 0, 6, nor -6, then the elements of *d* are also given a random sign (multiplied by +1 or -1).

cond

REAL for slatms and clatms

DOUBLE PRECISION for dlatms and zlatms

Used in setting *d* as described for the *mode* parameter. If used, $\text{cond} \geq 1$.

dmax

REAL for slatms and clatms

DOUBLE PRECISION for dlatms and zlatms

If *mode* is not -6, 0 nor 6, the contents of *d*, as computed according to *mode* and *cond*, are scaled by $d_{\max} / \max(\text{abs}(d(i)))$; thus, the maximum absolute eigenvalue or singular value (the norm) is $\text{abs}(d_{\max})$.

NOTE

dmax need not be positive: if *dmax* is negative (or zero), *d* will be scaled by a negative number (or zero).

kl

INTEGER. Specifies the lower bandwidth of the matrix. For example, *kl*=0 implies upper triangular, *kl*=1 implies upper Hessenberg, and *kl* being at least *m* - 1 means that the matrix has full lower bandwidth. *kl* must equal *ku* if the matrix is symmetric or Hermitian.

ku

INTEGER. Specifies the upper bandwidth of the matrix. For example, *ku*=0 implies lower triangular, *ku*=1 implies lower Hessenberg, and *ku* being at least *n* - 1 means that the matrix has full upper bandwidth. *kl* must equal *ku* if the matrix is symmetric or Hermitian.

pack

CHARACTER*1. Specifies packing of matrix:

- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
- 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
- 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
- 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store *A* in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

	'Z'	'B'	'Q'	'C'	'R'
GB: general band	x				
PB: symmetric positive definite band		x	x		
SB: symmetric band		x	x		
HB: Hermitian band		x	x		
TB: triangular band		x	x		
PP: symmetric positive definite packed				x	x
SP: symmetric packed				x	x
HP: Hermitian packed				x	x
TP: triangular packed				x	x

If two calls to `?latms` differ only in the `pack` parameter, they generate mathematically equivalent matrices.

lda

INTEGER. *lda* specifies the first dimension of *a* as declared in the calling program.

If `pack='N', 'U', 'L', 'C', or 'R'`, then *lda* must be at least *m*.

If `pack='B' or 'Q'`, then *lda* must be at least $\text{MIN}(kl, m - 1)$ (which is equal to $\text{MIN}(ku, n - 1)$).

If `pack='Z'`, *lda* must be large enough to hold the packed array: $\text{MIN}(ku, n - 1) + \text{MIN}(kl, m - 1) + 1$.

Output Parameters

iseed

The array *iseed* contains the updated seed.

d

The array *d* contains the updated seed.

NOTE

The array *d* is not modified if `mode = 0`.

a

REAL for `slatms`

DOUBLE PRECISION for `dlatms`

COMPLEX for `clatms`

DOUBLE COMPLEX for `zlatms`

Array of size *lda* by *n*.

The array *a* contains the generated *m*-by-*n* matrix *A*.

a is first generated in full (unpacked) form, and then packed, if so specified by `pack`. Thus, the first *m* elements of the first *n* columns are always modified. If `pack` specifies a packed or banded storage scheme, all *lda*

elements of the first n columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

work

REAL for slatms
DOUBLE PRECISION for dlatms
COMPLEX for clatms
DOUBLE COMPLEX for zlatms
Array of size $(3 \cdot \text{MAX}(n, m))$
Workspace.

info

INTEGER. If *info* = 0, the execution is successful.
If *info* < 0, the *i*-th parameter had an illegal value.
If *info* = -1011, memory allocation error occurred.
If *info* = 2, cannot scale to *dmax* (maximum singular value is 0).
If *info* = 3, error return from [lagge](#), [?laghe](#), or [lagsy](#).

ScaLAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complexm, and double complex precision. See the `mkl_scalapack.h` header file for C declarations of ScaLAPACK routines.

NOTE

ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

Sections in this chapter include descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call.

The `<install_directory>/examples/scalapackf` directory contains sample code demonstrating the use of ScaLAPACK routines.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also gives the opportunity to use BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix (array) and its corresponding process and memory location is contained in the array called the *array descriptor* associated with each global matrix. The size of the array descriptor is denoted as *dlen_*.

Let A be a two-dimensional block cyclicly distributed matrix with the array descriptor array *desca*. The meaning of each array descriptor element depends on the type of the matrix A . The tables [Array descriptor for dense matrices](#) and [Array descriptor for narrow-band and tridiagonal matrices](#) describe the meaning of each element for the different types of matrices.

Array descriptor for dense matrices (*dlen_=9*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca(dtype_)</i>	Descriptor type (=1 for dense matrices).	1
<i>ctxt_a</i>	<i>desca(ctxt_)</i>	BLACS context handle for the process grid.	2
<i>m_a</i>	<i>desca(m_)</i>	Number of rows in the global matrix A .	3
<i>n_a</i>	<i>desca(n_)</i>	Number of columns in the global matrix A .	4
<i>mb_a</i>	<i>desca(mb_)</i>	Row blocking factor.	5
<i>nb_a</i>	<i>desca(nb_)</i>	Column blocking factor.	6
<i>rsrc_a</i>	<i>desca(rsrc_)</i>	Process row over which the first row of the global matrix A is distributed.	7
<i>csrc_a</i>	<i>desca(csrc_)</i>	Process column over which the first column of the global matrix A is distributed.	8
<i>lld_a</i>	<i>desca(lld_)</i>	Leading dimension of the local matrix A .	9

Array descriptor for narrow-band and tridiagonal matrices (*dlen_=7*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca(dtype_)</i>	Descriptor type <ul style="list-style-type: none"> <i>dtype_a</i>=501: 1-by-P grid, <i>dtype_a</i>=502: P-by-1 grid. 	1
<i>ctxt_a</i>	<i>desca(ctxt_)</i>	BLACS context handle indicating the BLACS process grid over which the global matrix A is distributed. The context itself is global, but the handle (the integer value) can vary.	2
<i>n_a</i>	<i>desca(n_)</i>	The size of the matrix dimension being distributed.	3
<i>nb_a</i>	<i>desca(nb_)</i>	The blocking factor used to distribute the distributed dimension of the matrix A .	4
<i>src_a</i>	<i>desca(src_)</i>	The process row or column over which the first row or column of the matrix A is distributed.	5
<i>lld_a</i>	<i>desca(lld_)</i>	The leading dimension of the local matrix storing the local blocks of the distributed matrix A . The minimum value of <i>lld_a</i> depends on <i>dtype_a</i> . <ul style="list-style-type: none"> <i>dtype_a</i>=501: $lld_a \geq \max(\text{size of undistributed dimension}, 1)$, <i>dtype_a</i>=502: $lld_a \geq \max(nb_a, 1)$. 	6
Not applicable		Reserved for future use.	7

Similar notations are used for different matrices. For example: *lld_b* is the leading dimension of the local matrix storing the local blocks of the distributed matrix B and *dtype_z* is the type of the global matrix Z .

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix $\text{sub}(A)$ of the global matrix A defined by the following 6 values (for dense matrices):

m	The number of rows of $\text{sub}(A)$
n	The number of columns of $\text{sub}(A)$

<i>a</i>	A pointer to the local matrix containing the entire global matrix <i>A</i>
<i>ia</i>	The row index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>ja</i>	The column index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>desca</i>	The array descriptor for the global matrix <i>A</i>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Routine Naming Conventions

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

ScaLAPACK names have the structure *p?yyzzz* or *p?yyzz*, which is described below.

The initial letter *p* is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

<i>s</i>	real, single precision
<i>d</i>	real, double precision
<i>c</i>	complex, single precision
<i>z</i>	complex, double precision

The second and third letters *yy* indicate the matrix type as:

<i>ge</i>	general
<i>gb</i>	general band
<i>gg</i>	a pair of general matrices (for a generalized problem)
<i>dt</i>	general tridiagonal (diagonally dominant-like)
<i>db</i>	general band (diagonally dominant-like)
<i>po</i>	symmetric or Hermitian positive-definite
<i>pb</i>	symmetric or Hermitian positive-definite band
<i>pt</i>	symmetric or Hermitian positive-definite tridiagonal
<i>sy</i>	symmetric

st	symmetric tridiagonal (real)
he	Hermitian
or	orthogonal
tr	triangular (or quasi-triangular)
tz	trapezoidal
un	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

sv	a <i>simple</i> driver for solving a linear system
svx	an <i>expert</i> driver for solving a linear system
ls	a driver for solving a linear least squares problem
ev	a simple driver for solving a symmetric eigenvalue problem
evd	a simple driver for solving an eigenvalue problem using a divide and conquer algorithm
evx	an expert driver for solving a symmetric eigenvalue problem
svd	a driver for computing a singular value decomposition
gvx	an expert driver for solving a generalized symmetric definite eigenvalue problem

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Linear Equations

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded

- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See Table “Computational Routines for Systems of Linear Equations” for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding *driver routine* that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (*LU* factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

Table “Computational Routines for Systems of Linear Equations” lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	<code>p?getrf</code>	<code>p?geequ</code>	<code>p?getrs</code>	<code>p?gecon</code>	<code>p?gerfs</code>	<code>p?getri</code>
general band (partial pivoting)	<code>p?gbtrf</code>		<code>p?gbtrs</code>			
general band (no pivoting)	<code>p?dbtrf</code>		<code>p?dbtrs</code>			
general tridiagonal (no pivoting)	<code>p?dttrf</code>		<code>p?dttrs</code>			
symmetric/Hermitian positive-definite	<code>p?potrf</code>	<code>p?poequ</code>	<code>p?potrs</code>	<code>p?pocon</code>	<code>p?porfs</code>	<code>p?potri</code>
symmetric/Hermitian positive-definite, band	<code>p?pbtrf</code>		<code>p?pbtrs</code>			
symmetric/Hermitian positive-definite, tridiagonal	<code>p?pttrf</code>		<code>p?pttrs</code>			
triangular			<code>p?trtrs</code>	<code>p?trcon</code>	<code>p?trrfs</code>	<code>p?trtri</code>

In this table ? stands for *s* (single precision real), *d* (double precision real), *c* (single precision complex), or *z* (double precision complex).

Routines for Matrix Factorization

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

`p?getrf`

Computes the LU factorization of a general m-by-n distributed matrix.

Syntax

```
call psgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pdgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pcgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pzgetrf(m, n, a, ia, ja, desca, ipiv, info)
```

Include Files

Description

The `p?getrf` routine forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The routine uses partial pivoting, with row interchanges.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$; $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$; $n \geq 0$.
<i>a</i>	(local) REAL for <code>psgetrf</code> DOUBLE PRECISION for <code>pdgetrf</code> COMPLEX for <code>pcgetrf</code> DOUBLE COMPLEX for <code>pzgetrf</code> . Pointer into the local memory to an array of local size $(lld_a, LOCc(ja + n - 1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size $d/en_$. The array descriptor for the distributed matrix A .

Output Parameters

<i>a</i>	Overwritten by local pieces of the factors L and U from the factorization $A = P * L * U$. The unit diagonal elements of L are not stored.
<i>ipiv</i>	(local) INTEGER Array of size $LOCr(m_a) + mb_a$.

Contains the pivoting information: local row i was interchanged with global row $ipiv(i)$. This array is tied to the distributed matrix A .

info

(global) INTEGER.

If $info=0$, the execution is successful.

$info < 0$: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info = i > 0$, $u_{ia+i, ja+j-1}$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gbtrf

Computes the LU factorization of a general n -by- n banded distributed matrix.

Syntax

```
call psgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pdgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pcgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pzgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
```

Include Files

Description

The `p?gbtrf` routine computes the LU factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK routine `?gbtrf`. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P * L * U * Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Notice revision #20110804

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>a</i>	<p>(local)</p> <p>REAL for <code>psgbtrf</code> DOUBLE PRECISION for <code>pdgbtrf</code> COMPLEX for <code>pcgbtrf</code> DOUBLE COMPLEX for <code>pzgbtrf</code>.</p> <p>Pointer into the local memory to an array of local size (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i> + <i>n</i> - 1)) where</p> $lld_a \geq 2*bwl + 2*bwu + 1.$ <p>Contains the local pieces of the <i>n</i>-by-<i>n</i> distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.</p>
<i>ja</i>	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix A.</p> <p>If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.</p>
<i>laf</i>	<p>(local) INTEGER. The size of the array <i>af</i>.</p> <p>Must be $laf \geq (nb_a + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$.</p> <p>If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array ($lwork \geq 1$). If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned.

Output Parameters

<i>a</i>	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>ipiv</i>	(local) INTEGER array. The size of <i>ipiv</i> must be $\geq nb_a$. Contains pivot indices for local factorizations. Note that you <i>should not alter</i> the contents of this array between factorization and solve.
<i>af</i>	(local) REAL for psgbtrf DOUBLE PRECISION for pdgbtrf COMPLEX for pcgbtrf DOUBLE COMPLEX for pzgbtrf. Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization routine p?gbtrf and is stored in <i>af</i> . Note that if a linear system is to be solved using p?gbtrs after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required.
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not nonsingular, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbtrf

Computes the LU factorization of a n-by-n diagonally dominant-like banded distributed matrix.

Syntax

```
call psdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pddbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
```

```
call p?dbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pzdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
```

Include Files

Description

The `p?dbtrf` routine computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

NOTE

A matrix is called *diagonally dominant-like* if pivoting is not required for LU to be numerically stable.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Notice revision #20110804

Input Parameters

n (global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).

dl, d, du (local)

REAL for `pspttrf`
 DOUBLE PRECISION for `pdpttrf`
 COMPLEX for `pcpttrf`
 DOUBLE COMPLEX for `pzpttrf`.

Pointers to the local arrays of size nb_a each.

On entry, the array dl contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, $dl(1)$ is not referenced, and dl must be aligned with d .

On entry, the array d contains the local part of the global vector storing the diagonal elements of the matrix.

On entry, the array du contains the local part of the global vector storing the super-diagonal elements of the matrix. $du(n)$ is not referenced, and du must be aligned with d .

ja (global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

$desca$ (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

If $dtype_a = 501$, then $dlen_ \geq 7$;
 else if $dtype_a = 1$, then $dlen_ \geq 9$.

laf (local) INTEGER. The size of the array af .
 Must be $laf \geq 2*(NB+2)$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af(1)$.

$work$ (local) Same type as d . Workspace array of size $lwork$.

$lwork$ (local or global) INTEGER. The size of the $work$ array, must be at least $lwork \geq 8*NPCOL$.

Output Parameters

dl, d, du On exit, overwritten by the information containing the factors of the matrix.

af (local)
 REAL for `psdttrf`
 DOUBLE PRECISION for `pddttrf`
 COMPLEX for `pcdttrf`
 DOUBLE COMPLEX for `pzdttrf`.

Array of size laf .

Auxiliary fill-in space. The fill-in space is created in a call to the factorization routine `p?dttrf` and is stored in af .

Note that if a linear system is to be solved using `p?dtttrs` after the factorization routine, `af` must not be altered.

`work(1)`

On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.

If `info=0`, the execution is successful.

`info < 0`:

If the i -th argument is an array and the j -th entry had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

`info > 0`:

If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not diagonally dominant-like, and the factorization was not completed.

If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```
call pspotrf(uplo, n, a, ia, ja, desca, info)
call pdpotrf(uplo, n, a, ia, ja, desca, info)
call pcpotrf(uplo, n, a, ia, ja, desca, info)
call pzpotrf(uplo, n, a, ia, ja, desca, info)
```

Include Files

Description

The `p?potrf` routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $\text{sub}(A)$.

The factorization has the form

$\text{sub}(A) = U^H * U$ if `uplo='U'`, or

$\text{sub}(A) = L * L^H$ if `uplo='L'`

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

`uplo`

(global) CHARACTER*1.

Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. Must be 'U' or 'L'.

If $\text{uplo} = \text{'U'}$, the array a stores the upper triangular part of the matrix $\text{sub}(A)$ that is factored as $U^H * U$.

If $\text{uplo} = \text{'L'}$, the array a stores the lower triangular part of the matrix $\text{sub}(A)$ that is factored as $L * L^H$.

n (global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

a (local)
 REAL for pspotrff
 DOUBLE PRECISION for pdpotrf
 COMPLEX for pcpotrff
 DOUBLE COMPLEX for pzpotrf.
 Pointer into the local memory to an array of size $(\text{lld}_a, \text{LOCc}(ja+n-1))$.
 On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$ to be factored.
 Depending on uplo , the array a contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see uplo).

ia, ja (global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

$desca$ (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

Output Parameters

a The upper or lower triangular part of a is overwritten by the Cholesky factor U or L , as specified by uplo .

$info$ (global) INTEGER.
 If $info=0$, the execution is successful;
 $info < 0$: if the i -th argument is an array, and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.
 If $info = k > 0$, the leading minor of order k , $A(ia:ia+k-1, ja:ja+k-1)$, is not positive-definite, and the factorization could not be completed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite banded distributed matrix.

Syntax

```
call pspbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pdpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pcpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pzpbtfrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
```

Include Files

Description

The `p?pbtrf` routine computes the Cholesky factorization of an n -by- n real symmetric or complex Hermitian positive-definite banded distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P*U^H*U*P^T$, if `uplo='U'`, or

$A(1:n, ja:ja+n-1) = P*L*L^H*P^T$, if `uplo='L'`,

where P is a permutation matrix and U and L are banded upper and lower triangular matrices, respectively.

Notice revision #20110804

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <code>uplo = 'L'</code> , lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$. ($n \geq 0$).
<code>bw</code>	(global) INTEGER. The number of superdiagonals of the distributed matrix if <code>uplo = 'U'</code> , or the number of subdiagonals if <code>uplo = 'L'</code> ($bw \geq 0$).
<code>a</code>	(local) REAL for <code>pspbtrf</code> DOUBLE PRECISION for <code>pdpbtrf</code>

COMPLEX for `pcpbtrf`

DOUBLE COMPLEX for `pzpbtrf`.

Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$.

On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored.

ja (global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A .

If *dtype_a* = 501, then $dlen_ \geq 7$;

else if *dtype_a* = 1, then $dlen_ \geq 9$.

laf (local) INTEGER. The size of the array *af*.

Must be $laf \geq (NB+2*bw) * bw$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local) Same type as *a*. Workspace array of size *lwork*.

lwork (local or global) INTEGER. The size of the *work* array, must be $lwork \geq bw^2$.

Output Parameters

a On exit, if *info*=0, contains the permuted triangular factor U or L from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$, as specified by *uplo*.

af (local)

REAL for `pspbtrf`

DOUBLE PRECISION for `pdpbtrf`

COMPLEX for `pcpbtrf`

DOUBLE COMPLEX for `pzpbtrf`.

Array of size *laf*. Auxiliary fill-in space. The fill-in space is created in a call to the factorization routine `p?pbtrf` and stored in *af*. Note that if a linear system is to be solved using `p?pbtrs` after the factorization routine, *af* must not be altered.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.

If *info*=0, the execution is successful.

info < 0:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k \leq NPROCS$, the submatrix stored on processor $info$ and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?pttrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite tridiagonal distributed matrix.

Syntax

```
call pspttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pdpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pcpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pzpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
```

Include Files

Description

The `p?pttrf` routine computes the Cholesky factorization of an n -by- n real symmetric or complex hermitian positive-definite tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P * L * D * L^H * P^T, \text{ or}$$

$$A(1:n, ja:ja+n-1) = P * U^H * D * U * P^T,$$

where P is a permutation matrix, and U and L are tridiagonal upper and lower triangular matrices, respectively.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
<i>d, e</i>	(local) REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Pointers into the local memory to arrays of size <i>nb_a</i> each. On entry, the array <i>d</i> contains the local part of the global vector storing the main diagonal of the distributed matrix <i>A</i> . On entry, the array <i>e</i> contains the local part of the global vector storing the upper diagonal of the distributed matrix <i>A</i> .
<i>ja</i>	(global) INTEGER. The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7 ; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9 .
<i>laf</i>	(local) INTEGER. The size of the array <i>af</i> . Must be <i>laf</i> $\geq nb_a + 2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>d</i> and <i>e</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least <i>lwork</i> $\geq 8 * NPCOL$.

Output Parameters

<i>d, e</i>	On exit, overwritten by the details of the factorization.
<i>af</i>	(local) REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Array of size <i>laf</i> .

Auxiliary fill-in space. The fill-in space is created in a call to the factorization routine `p?pttrf` and stored in `af`.

Note that if a linear system is to be solved using `p?pttrs` after the factorization routine, `af` must not be altered.

`work(1)`

On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.

If `info=0`, the execution is successful.

`info < 0`:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

`info > 0`:

If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not positive definite, and the factorization was not completed.

If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

Routines for Solving Systems of Linear Equations

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by `p?getrf`.

Syntax

```
call psgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Include Files

Description

The `p?getrs` routine solves a system of distributed linear equations with a general *n*-by-*n* distributed matrix `sub(A) = A(ia:ia+n-1, ja:ja+n-1)` using the *LU* factorization computed by `p?getrf`.

The system has one of the following forms specified by `trans`:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),
 $\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),
 $\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),
 where $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$.

Before calling this routine, you must call `p?getrf` to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	<p>(global) CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Indicates the form of the equations:</p> <p>If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X.</p> <p>If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X.</p> <p>If <i>trans</i> = 'C', then $\text{sub}(A)^H *X = \text{sub}(B)$ is solved for X.</p>
<i>n</i>	<p>(global) INTEGER. The number of linear equations; the order of the matrix $\text{sub}(A)$ ($n \geq 0$).</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).</p>
<i>a, b</i>	<p>(global)</p> <p>REAL for <code>psgetrs</code></p> <p>DOUBLE PRECISION for <code>pdgetrs</code></p> <p>COMPLEX for <code>pcgetrs</code></p> <p>DOUBLE COMPLEX for <code>pzgetrs</code>.</p> <p>Pointers into the local memory to arrays of local sizes $(lld_a, LOCc(ja + n - 1))$ and $(lld_b, LOCc(jb + nrhs - 1))$, respectively.</p> <p>On entry, the array <i>a</i> contains the local pieces of the factors L and U from the factorization $\text{sub}(A) = P*L*U$; the unit diagonal elements of L are not stored. On entry, the array <i>b</i> contains the right hand sides $\text{sub}(B)$.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix A.</p>
<i>ipiv</i>	<p>(local) INTEGER Array of size of $LOCr(m_a) + mb_a$. Contains the pivoting information: local row i of the matrix was interchanged with the global row <i>ipiv</i>(i).</p> <p>This array is tied to the distributed matrix A.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the matrix $\text{sub}(B)$, respectively.</p>

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

b On exit, overwritten by the solution distributed matrix *X*.

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?gbtrs

Solves a system of distributed linear equations with a general band matrix, using the LU factorization computed by p?gbtrf.

Syntax

```
call psgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pdgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pcgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)
```

```
call pzgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af, laf,
work, lwork, info)
```

Include Files

Description

The `p?gbtrs` routine solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the *LU* factorization computed by `p?gbtrf`.

The system has one of the following forms specified by *trans*:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this routine, you must call `p?gbtrf` to compute the *LU* factorization of $\text{sub}(A)$.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If *trans* = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for *X*.

	<p>If $trans = 'T'$, then $sub(A)^T * X = sub(B)$ is solved for X.</p> <p>If $trans = 'C'$, then $sub(A)^H * X = sub(B)$ is solved for X.</p>
n	(global) INTEGER. The number of linear equations; the order of the distributed matrix $sub(A)$ ($n \geq 0$).
bwl	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
bwu	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
$nrhs$	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $sub(B)$ ($nrhs \geq 0$).
a, b	<p>(global)</p> <p>REAL for <code>psgbtrs</code></p> <p>DOUBLE PRECISION for <code>pdgbtrs</code></p> <p>COMPLEX for <code>pcgbtrs</code></p> <p>DOUBLE COMPLEX for <code>pzgbtrs</code>.</p> <p>Pointers into the local memory to arrays of local sizes ($lld_a, LOCc(ja + n - 1)$) and ($lld_b, LOCc(nrhs)$), respectively.</p> <p>The array a contains details of the LU factorization of the distributed band matrix A.</p> <p>On entry, the array b contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.</p>
ja	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	<p>(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A.</p> <p>If $dtype_a = 501$, then $dlen_ \geq 7$;</p> <p>else if $dtype_a = 1$, then $dlen_ \geq 9$.</p>
ib	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$descb$	<p>(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A.</p> <p>If $dtype_b = 502$, then $dlen_ \geq 7$;</p> <p>else if $dtype_b = 1$, then $dlen_ \geq 9$.</p>
laf	<p>(local) INTEGER. The size of the array af.</p> <p>Must be $laf \geq nb_a * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$.</p>

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local) Same type as *a*. Workspace array of size *lwork*.

lwork (local or global) INTEGER. The size of the *work* array, must be at least $lwork \geq nrhs * (nb_a + 2 * bwl + 4 * bwu)$.

Output Parameters

ipiv (local) INTEGER array.

The size of *ipiv* must be $\geq nb_a$.

Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.

b On exit, overwritten by the local pieces of the solution distributed matrix X.

af (local)

REAL for psgbtrs

DOUBLE PRECISION for pdgbtrs

COMPLEX for pcgbtrs

DOUBLE COMPLEX for pzgbtrs.

Array of size *laf*.

Auxiliary Fill-in space. The fill-in space is created in a call to the factorization routine *p?gbtrf* and is stored in *af*.

Note that if a linear system is to be solved using *p?gbtrs* after the factorization routine, *af* must not be altered after the factorization.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?dbtrs

Solves a system of linear equations with a diagonally dominant-like banded distributed matrix using the factorization computed by p?dbtrf.

Syntax

```
call psdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

```
call pddbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pcdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pzdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

Include Files

Description

The `p?dbtrs` routine solves for X one of the systems of equations:

$\text{sub}(A)*X = \text{sub}(B)$,
 $(\text{sub}(A))^T*X = \text{sub}(B)$, or
 $(\text{sub}(A))^H*X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by `p?dbtrf`.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $(\text{sub}(A))^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $(\text{sub}(A))^H*X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for psdbtrs DOUBLE PRECISION for pddbtrs COMPLEX for pcdbtrs DOUBLE COMPLEX for pzdbtrs. Pointers into the local memory to arrays of local sizes (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) and (<i>lld_b</i> , <i>LOCc(nrhs)</i>), respectively.

On entry, the array *a* contains details of the *LU* factorization of the band matrix *A*, as computed by `p?dbtrf`.

On entry, the array *b* contains the local pieces of the right hand side distributed matrix `sub(B)`.

ja (global) INTEGER. The index in the global matrix *A* indicating the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

If *dtype_a* = 501, then *dlen_* ≥ 7;

else if *dtype_a* = 1, then *dlen_* ≥ 9.

ib (global) INTEGER. The row index in the global matrix *B* indicating the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

If *dtype_b* = 502, then *dlen_* ≥ 7;

else if *dtype_b* = 1, then *dlen_* ≥ 9.

af, work

(local)

REAL for `psdbtrs`

DOUBLE PRECISION for `pddbtrs`

COMPLEX for `pcdbtrs`

DOUBLE COMPLEX for `pzdbtrs`.

Arrays of size *laf* and *lwork*, respectively The array *af* contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine `p?dbtrf` and is stored in *af*.

The array *work* is a workspace array.

laf (local) INTEGER. The size of the array *af*.

Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

lwork

(local or global) INTEGER. The size of the array *work*, must be at least

$lwork \geq (\max(bwl, bwu))^2$.

Output Parameters

b On exit, this array contains the local pieces of the solution distributed matrix *X*.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?dttrs

Solves a system of linear equations with a diagonally dominant-like tridiagonal distributed matrix using the factorization computed by p?dttrf.

Syntax

```
call psdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

```
call pddttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

```
call pcdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

```
call pzdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

Include Files

Description

The p?dttrs routine solves for X one of the systems of equations:

$\text{sub}(A) * X = \text{sub}(B)$,

$(\text{sub}(A))^T * X = \text{sub}(B)$, or

$(\text{sub}(A))^H * X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by p?dttrf.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .

If *trans* = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .

If *trans* = 'C', then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X .

n (global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

nrhs (global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).

<i>dl, d, du</i>	<p>(local)</p> <p>REAL for psdttrs</p> <p>DOUBLE PRECISION for pddttrs</p> <p>COMPLEX for pcdttrs</p> <p>DOUBLE COMPLEX for pzdttrs.</p> <p>Pointers to the local arrays of size <i>nb_a</i> each.</p> <p>On entry, these arrays contain details of the factorization. Globally, <i>dl</i>(1) and <i>du</i>(<i>n</i>) are not referenced; <i>dl</i> and <i>du</i> must be aligned with <i>d</i>.</p>
<i>ja</i>	<p>(global) INTEGER. The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p> <p>If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then <i>dlen_</i> ≥ 7;</p> <p>else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.</p>
<i>b</i>	<p>(local) Same type as <i>d</i>.</p> <p>Pointer into the local memory to an array of local size (<i>lld_b</i>, <i>LOCc</i>(<i>nrhs</i>))</p> <p>On entry, the array <i>b</i> contains the local pieces of the <i>n</i>-by-<i>nrhs</i> right hand side distributed matrix sub(<i>B</i>).</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>B</i>.</p> <p>If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7;</p> <p>else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.</p>
<i>af, work</i>	<p>(local) REAL for psdttrs</p> <p>DOUBLE PRECISION for pddttrs</p> <p>COMPLEX for pcdttrs</p> <p>DOUBLE COMPLEX for pzdttrs.</p> <p>Arrays of size <i>laf</i> and (<i>lwork</i>), respectively.</p> <p>The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine <i>p?dttrf</i> and is stored in <i>af</i>. If a linear system is to be solved using <i>p?dttrs</i> after the factorization routine, <i>af</i> must not be altered.</p> <p>The array <i>work</i> is a workspace array.</p>
<i>laf</i>	<p>(local) INTEGER. The size of the array <i>af</i>.</p>

Must be $laf \geq NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af(1)$.

$lwork$ (local or global) INTEGER. The size of the array $work$, must be at least $lwork \geq 10 * NPCOL + 4 * nrhs$.

Output Parameters

b On exit, this array contains the local pieces of the solution distributed matrix X .

$work(1)$ On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$ INTEGER. If $info=0$, the execution is successful. $info < 0$:
If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?potrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian distributed positive-definite matrix.

Syntax

```
call pspotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzpotsrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Include Files

Description

The p?potrs routine solves for X a system of distributed linear equations in the form:

$\text{sub}(A) * X = \text{sub}(B)$,

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

This routine uses Cholesky factorization

$\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$

computed by [p?potrf](#).

Input Parameters

$uplo$ (global) CHARACTER*1. Must be 'U' or 'L'.

	<p>If <code>uplo = 'U'</code>, upper triangle of <code>sub(A)</code> is stored;</p> <p>If <code>uplo = 'L'</code>, lower triangle of <code>sub(A)</code> is stored.</p>
<code>n</code>	(global) INTEGER. The order of the distributed matrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix <code>sub(B)</code> ($nrhs \geq 0$).
<code>a, b</code>	<p>(local)</p> <p>REAL for <code>pspotrs</code></p> <p>DOUBLE PRECISION for <code>pdpotrs</code></p> <p>COMPLEX for <code>pcpotrs</code></p> <p>DOUBLE COMPLEX for <code>pzpotrs</code>.</p> <p>Pointers into the local memory to arrays of local sizes</p> <p><code>(lld_a, LOCC(ja+n-1))</code> and <code>(lld_b, LOCC(jb+nrhs-1))</code>, respectively.</p> <p>The array <code>a</code> contains the factors <code>L</code> or <code>U</code> from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by <code>p?potrf</code>.</p> <p>On entry, the array <code>b</code> contains the local pieces of the right hand sides <code>sub(B)</code>.</p>
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global matrix <code>A</code> indicating the first row and the first column of the matrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>A</code> .
<code>ib, jb</code>	(global) INTEGER. The row and column indices in the global matrix <code>B</code> indicating the first row and the first column of the matrix <code>sub(B)</code> , respectively.
<code>descb</code>	(local) INTEGER array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>B</code> .

Output Parameters

<code>b</code>	Overwritten by the local pieces of the solution matrix <code>X</code> .
<code>info</code>	<p>INTEGER. If <code>info=0</code>, the execution is successful.</p> <p><code>info < 0</code>: if the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then <code>info = -(i*100+j)</code>; if the <i>i</i>-th argument is a scalar and had an illegal value, then <code>info = -i</code>.</p>

p?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian positive-definite band matrix.

Syntax

```
call pspbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pdpbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pcpbtrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

```
call pzpbttrs(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work, lwork,
info)
```

Include Files

Description

The `p?pbttrs` routine solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses Cholesky factorization

$$\text{sub}(A) = P * U^H * U * P^T, \text{ or } \text{sub}(A) = P * L * L^H * P^T$$

computed by `p?pbttrf`.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L' ($bw \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for <code>pspbtrs</code> DOUBLE PRECISION for <code>pdpbtrs</code> COMPLEX for <code>pcpbtrs</code> DOUBLE COMPLEX for <code>pzpbttrs</code> . Pointers into the local memory to arrays of local sizes $(lld_a, LOCC(ja+n-1))$ and $(lld_b, LOCC(nrhs-1))$, respectively. The array <i>a</i> contains the permuted triangular factor U or L from the Cholesky factorization $\text{sub}(A) = P * U^H * U * P^T$, or $\text{sub}(A) = P * L * L^H * P^T$ of the band matrix <i>A</i> , as returned by <code>p?pbttrf</code> .

	On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix <i>sub</i> (<i>B</i>).
<i>ja</i>	(global) INTEGER. The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) INTEGER. The row index in the global matrix <i>B</i> indicating the first row of the matrix <i>sub</i> (<i>B</i>).
<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) Arrays, same type as <i>a</i> . The array <i>af</i> is of size <i>laf</i> . It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine p?dbtrf and is stored in <i>af</i> . The array <i>work</i> is a workspace array of size <i>lwork</i> .
<i>laf</i>	(local) INTEGER. The size of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nrhs</i> * <i>bw</i> . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least <i>lwork</i> ≥ <i>bw</i> ² .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, this array contains the local pieces of the <i>n</i> -by- <i>nrhs</i> solution distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal distributed matrix using the factorization computed by p?pttrf.

Syntax

```
call pspttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pdpttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Include Files**Description**

The p?pttrs routine solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the factorization

$$\text{sub}(A) = P * L * D * L^H * P^T, \text{ or } \text{sub}(A) = P * U^H * D * U * P^T$$

computed by p?pttrf.

Input Parameters

<i>uplo</i>	(global, used in complex flavors only) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>d, e</i>	(local) REAL for pspttrs DOUBLE PRECISION for pdpttrs COMPLEX for pcpttrs DOUBLE COMPLEX for pzpttrs. Pointers into the local memory to arrays of size <i>nb_a</i> each. These arrays contain details of the factorization as returned by p?pttrf
<i>ja</i>	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p> <p>If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then <i>dlen_</i> ≥ 7;</p> <p>else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.</p>
<i>b</i>	<p>(local) Same type as <i>d</i>, <i>e</i>.</p> <p>Pointer into the local memory to an array of local size</p> <p>(<i>lld_b</i>, <i>LOCc</i>(<i>nrhs</i>)).</p> <p>On entry, the array <i>b</i> contains the local pieces of the <i>n</i>-by-<i>nrhs</i> right hand side distributed matrix sub(<i>B</i>).</p>
<i>ib</i>	<p>(global) INTEGER. The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).</p>
<i>descb</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>B</i>.</p> <p>If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7;</p> <p>else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.</p>
<i>af</i> , <i>work</i>	<p>(local) REAL for <i>pspttrs</i></p> <p>DOUBLE PRECISION for <i>pdpttrs</i></p> <p>COMPLEX for <i>pcpttrs</i></p> <p>DOUBLE COMPLEX for <i>pzpttrs</i>.</p> <p>Arrays of size <i>laf</i> and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization routine <i>p?pttrf</i> and is stored in <i>af</i>.</p> <p>The array <i>work</i> is a workspace array.</p>
<i>laf</i>	<p>(local) INTEGER. The size of the array <i>af</i>.</p> <p>Must be <i>laf</i> ≥ <i>nb_a</i> + 2.</p> <p>If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i>(1).</p>
<i>lwork</i>	<p>(local or global) INTEGER. The size of the array <i>work</i>, must be at least</p> <p><i>lwork</i> ≥ (10 + 2 * <i>min</i>(100, <i>nrhs</i>)) * NPCOL + 4 * <i>nrhs</i>.</p>

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	<p>INTEGER. If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> < 0:</p>

if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?trtrs

Solves a system of linear equations with a triangular distributed matrix.

Syntax

```
call pstrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdtrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pctrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pztrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Include Files

Description

The `p?trtrs` routine solves for X one of the following systems of linear equations:

$\text{sub}(A)*X = \text{sub}(B)$,

$(\text{sub}(A))^T*X = \text{sub}(B)$, or

$(\text{sub}(A))^H*X = \text{sub}(B)$,

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Indicates whether $\text{sub}(A)$ is upper or lower triangular: If <i>uplo</i> = 'U', then $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', then $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $\text{sub}(A)^H*X = \text{sub}(B)$ is solved for X .
<i>diag</i>	(global) CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then $\text{sub}(A)$ is not a unit triangular matrix. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; i.e., the number of columns of the distributed matrix sub(<i>B</i>) (<i>nrhs</i> ≥0).
<i>a, b</i>	<p>(local)</p> <p>REAL for pstrtrs</p> <p>DOUBLE PRECISION for pdtrtrs</p> <p>COMPLEX for pctrtrs</p> <p>DOUBLE COMPLEX for pztrtrs.</p> <p>Pointers into the local memory to arrays of local sizes (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>) and (<i>lld_b</i>, <i>LOCc(jb+nrhs-1)</i>), respectively.</p> <p>The array <i>a</i> contains the local pieces of the distributed triangular matrix sub(<i>A</i>).</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular matrix, and the strictly lower triangular part of sub(<i>A</i>) is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular matrix, and the strictly upper triangular part of sub(<i>A</i>) is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of sub(<i>A</i>) are also not referenced and are assumed to be 1.</p> <p>On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix sub(<i>B</i>).</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, sub(<i>B</i>) is overwritten by the solution matrix <i>X</i> .
<i>info</i>	<p>INTEGER. If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> < 0:</p> <p>if the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p> <p><i>info</i> > 0:</p>

if $info = i$, the i -th diagonal element of $sub(A)$ is zero, indicating that the submatrix is singular and the solutions X have not been computed.

Routines for Estimating the Condition Number

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

```
call psgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pdgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork, liwork,
info)

call pcgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)

call pzgecon(norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork,
info)
```

Include Files

Description

The `p?gecon` routine estimates the reciprocal of the condition number of a general distributed real/complex matrix $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$ in either the 1-norm or infinity-norm, using the LU factorization computed by `p?getrf`.

An estimate is obtained for $|(sub(A))^{-1}|$, and the reciprocal of the condition number is computed as

.....

Input Parameters

norm (global) CHARACTER*1. Must be '1' or 'O' or 'I'.
Specifies whether the 1-norm condition number or the infinity-norm condition number is required.
If *norm* = '1' or 'O', then the 1-norm is used;
If *norm* = 'I', then the infinity-norm is used.

<i>n</i>	(global) INTEGER. The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	<p>(local)</p> <p>REAL for psgecon</p> <p>DOUBLE PRECISION for pdgecon</p> <p>COMPLEX for pcgecon</p> <p>DOUBLE COMPLEX for pzgecon.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCc(ja+n-1))$.</p> <p>The array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $sub(A) = P*L*U$; the unit diagonal elements of <i>L</i> are not stored.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	<p>(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors.</p> <p>If <i>norm</i> = '1' or 'O', the 1-norm of the original distributed matrix sub(<i>A</i>);</p> <p>If <i>norm</i> = 'I', the infinity-norm of the original distributed matrix sub(<i>A</i>).</p>
<i>work</i>	<p>(local)</p> <p>REAL for psgecon</p> <p>DOUBLE PRECISION for pdgecon</p> <p>COMPLEX for pcgecon</p> <p>DOUBLE COMPLEX for pzgecon.</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The size of the array <i>work</i>.</p> <p>For real flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+mod(ia-1, mb_a)) + 2*LOCc(n+mod(ja-1, nb_a)) + \max(2, \max(nb_a*\max(1, iceil(NPROW-1, NPCOL)), LOCc(n+mod(ja-1, nb_a)) + nb_a*\max(1, iceil(NPCOL-1, NPROW))))).$ <p>For complex flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2*LOCr(n+mod(ia-1, mb_a)) + \max(2, \max(nb_a*iceil(NPROW-1, NPCOL), LOCc(n+mod(ja-1, nb_a)) + nb_a*iceil(NPCOL-1, NPROW))).$ <p><i>LOCr</i> and <i>LOCc</i> values can be computed using the ScaLAPACK tool function numroc; NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.</p>

NOTE

$\text{iceil}(x, y)$ is the ceiling of x/y , and $\text{mod}(x, y)$ is the integer remainder of x/y .

<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia-1, mb_a)).$
<i>rwork</i>	(local) REAL for pcgecon DOUBLE PRECISION for pzgecon Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq \max(1, 2 * LOCc(n + \text{mod}(ja-1, nb_a))).$

Output Parameters

<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The reciprocal of the condition number of the distributed matrix sub(A). See Description.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. $info < 0$: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then $info = -(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$.

call pcpocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork, info)
```

```
call pzpocon(uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork, lrwork, info)
```

Include Files

Description

The `p?pocon` routine estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

An estimate is obtained for $||(\text{sub}(A))^{-1}||$, and the reciprocal of the condition number is computed as

.....

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the factor stored in $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ stores the upper triangular factor U of the Cholesky factorization $\text{sub}(A) = U^H * U$. If <i>uplo</i> = 'L', $\text{sub}(A)$ stores the lower triangular factor L of the Cholesky factorization $\text{sub}(A) = L * L^H$.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pspocon DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon. Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. The array <i>a</i> contains the local pieces of the factors L or U from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by <code>p?potrf</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors. The 1-norm of the symmetric/Hermitian distributed matrix <i>sub(A)</i> .
<i>work</i>	(local) REAL for pspocn DOUBLE PRECISION for pdpocn COMPLEX for pcpcn DOUBLE COMPLEX for pzpcn. The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+2*LOCc(n+mod(ja-1,nb_a))$ $+max(2, max(nb_a*iceil(NPROW-1, NPCOL), LOCc(n$ $+mod(ja-1,nb_a))+nb_a*iceil(NPCOL-1, NPROW)).$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb_a))+max(2,$ $max(nb_a*max(1,iceil(NPROW-1, NPCOL)), LOCc(n+mod(ja-1,nb_a))$ $+nb_a*max(1,iceil(NPCOL-1, NPROW))).$
<hr/> <p>NOTE iceil(<i>x</i>,<i>y</i>) is the ceiling of <i>x/y</i>, and mod(<i>x</i>,<i>y</i>) is the integer remainder of <i>x/y</i>.</p> <hr/>	
<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ia-1,mb_a))$.
<i>rwork</i>	(local) REAL for pcpcn DOUBLE PRECISION for pzpcn Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+mod(ja-1,nb_a))$.
Output Parameters	
<i>rcond</i>	(global) REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

The reciprocal of the condition number of the distributed matrix $\text{sub}(A)$.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1) On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1) On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?trcon

Estimates the reciprocal of the condition number of a triangular distributed matrix in either 1-norm or infinity-norm.

Syntax

```
call pstrcon(norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, iwork, liwork, info)
```

```
call pdtrcon(norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, iwork, liwork, info)
```

```
call pctrcon(norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, rwork, lrwork, info)
```

```
call pztrcon(norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork, rwork, lrwork, info)
```

Include Files

Description

The *p?trcon* routine estimates the reciprocal of the condition number of a triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, in either the 1-norm or the infinity-norm.

The norm of $\text{sub}(A)$ is computed and an estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, then the reciprocal of the condition number is computed as

.....

Input Parameters

<i>norm</i>	<p>(global) CHARACTER*1. Must be '1' or 'O' or 'I'.</p> <p>Specifies whether the 1-norm condition number or the infinity-norm condition number is required.</p> <p>If <i>norm</i> = '1' or 'O', then the 1-norm is used;</p> <p>If <i>norm</i> = 'I', then the infinity-norm is used.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', sub(A) is upper triangular. If <i>uplo</i> = 'L', sub(A) is lower triangular.</p>
<i>diag</i>	<p>(global) CHARACTER*1. Must be 'N' or 'U'.</p> <p>If <i>diag</i> = 'N', sub(A) is non-unit triangular. If <i>diag</i> = 'U', sub(A) is unit triangular.</p>
<i>n</i>	(global) INTEGER. The order of the distributed matrix sub(A), ($n \geq 0$).
<i>a</i>	<p>(local)</p> <p>REAL for pstrcon</p> <p>DOUBLE PRECISION for pdtrcon</p> <p>COMPLEX for pctrcon</p> <p>DOUBLE COMPLEX for pztrcon.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$.</p> <p>The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A).</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	<p>(local)</p> <p>REAL for pstrcon</p> <p>DOUBLE PRECISION for pdtrcon</p> <p>COMPLEX for pctrcon</p> <p>DOUBLE COMPLEX for pztrcon.</p>

	<p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local or global) INTEGER. The size of the array <i>work</i>.</p> <p>For real flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb_a)) + LOCc(n + \text{mod}(ja - 1, nb_a)) + \max(2, \max(nb_a * \max(1, \text{iceil}(\text{NPROW} - 1, \text{NPCOL})), LOCc(n + \text{mod}(ja - 1, nb_a)) + nb_a * \max(1, \text{iceil}(\text{NPCOL} - 1, \text{NPROW}))))).$ <p>For complex flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb_a)) + \max(2, \max(nb_a * \text{iceil}(\text{NPROW} - 1, \text{NPCOL}), LOCc(n + \text{mod}(ja - 1, nb_a)) + nb_a * \text{iceil}(\text{NPCOL} - 1, \text{NPROW}))))).$ <hr/> <p>NOTE $\text{iceil}(x, y)$ is the ceiling of x/y, and $\text{mod}(x, y)$ is the integer remainder of x/y.</p> <hr/>
<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	<p>(local or global) INTEGER. The size of the array <i>iwork</i>; used in real flavors only. Must be at least</p> $liwork \geq LOCr(n + \text{mod}(ia - 1, mb_a)).$
<i>rwork</i>	<p>(local) REAL for pcpocon</p> <p>DOUBLE PRECISION for pzpocon</p> <p>Workspace array of size <i>lrwork</i>. Used in complex flavors only.</p>
<i>lrwork</i>	<p>(local or global) INTEGER. The size of the array <i>rwork</i>; used in complex flavors only. Must be at least</p> $lrwork \geq LOCc(n + \text{mod}(ja - 1, nb_a)).$
Output Parameters	
<i>rcond</i>	<p>(global) REAL for single precision flavors.</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>The reciprocal of the condition number of the distributed matrix sub(A).</p>
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Refining the Solution and Estimating Its Error

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

```
call psgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pdgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pcgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)

call pzgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv, b, ib, jb,
descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
```

Include Files

Description

The p?gerfs routine improves the computed solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$,

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$, or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ and provides error bounds and backward error estimates for the solution.

Here $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$, and $\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.

Specifies the form of the system of equations:

If *trans* = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose);

If *trans* = 'T', the system has the form $\text{sub}(A)^T \text{sub}(X) = \text{sub}(B)$ (Transpose);

If *trans* = 'C', the system has the form $\text{sub}(A)^H \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).

n (global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

nrhs (global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).

a, af, b, x

(local)

REAL for *psgerfs*

DOUBLE PRECISION for *pdgerfs*

COMPLEX for *pcgerfs*

DOUBLE COMPLEX for *pzgerfs*.

Pointers into the local memory to arrays of local sizes *a*(*lld_a*, *LOCc*(*ja* + *n* - 1)), *af*(*lld_af*, *LOCc*(*jaf* + *n* - 1)), *b*(*lld_b*, *LOCc*(*jb* + *nrhs* - 1)), and *x*(*lld_x*, *LOCc*(*jx* + *nrhs* - 1)), respectively.

The array *a* contains the local pieces of the distributed matrix $\text{sub}(A)$.

The array *af* contains the local pieces of the distributed factors of the matrix $\text{sub}(A) = P * L * U$ as computed by *p?getrf*.

The array *b* contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$.

On entry, the array *x* contains the local pieces of the distributed solution matrix $\text{sub}(X)$.

ia, ja (global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iaf, jaf (global) INTEGER. The row and column indices in the global matrix *AF* indicating the first row and the first column of the matrix $\text{sub}(AF)$, respectively.

descaf (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *AF*.

ib, jb (global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the matrix $\text{sub}(B)$, respectively.

descb (global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *B*.

ix, jx (global) INTEGER. The row and column indices in the global matrix *X* indicating the first row and the first column of the matrix $\text{sub}(X)$, respectively.

<i>descx</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>ipiv</i>	(local) INTEGER. Array of size $LOCr(m_af) + mb_af$. This array contains pivoting information as computed by <code>p?getrf</code> . If $ipiv(i)=j$, then the local row <i>i</i> was swapped with the global row <i>j</i> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>psgerfs</code> DOUBLE PRECISION for <code>pdgerfs</code> COMPLEX for <code>pcgerfs</code> DOUBLE COMPLEX for <code>pzgerfs</code> . The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$
<hr/> NOTE $\text{mod}(x, y)$ is the integer remainder of x/y . <hr/>	
<i>iwork</i>	(local) INTEGER. Workspace array, size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.
<i>rwork</i>	(local) REAL for <code>pcgerfs</code> DOUBLE PRECISION for <code>pzgerfs</code> Workspace array, size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr, berr</i>	REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays of size $LOCc(jb+nrhs-1)$ each.

The array *ferr* contains the estimated forward error bound for each solution vector of sub(X).

If XTRUE is the true solution corresponding to sub(X), *ferr* is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - \text{XTRUE})$ divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix X.

The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1)

On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1)

On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info

(global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

```

Include Files

Description

The `p?porfs` routine improves the computed solution to the system of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$$

are right-hand side and solution submatrices, respectively. This routine also provides error bounds and backward error estimates for the solution.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($\text{nrhs} \geq 0$).
<i>a</i> , <i>af</i> , <i>b</i> , <i>x</i>	(local) REAL for <code>psporfs</code> DOUBLE PRECISION for <code>pdporfs</code> COMPLEX for <code>pcporfs</code> DOUBLE COMPLEX for <code>pzporfs</code> . Pointers into the local memory to arrays of local sizes $a(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$, $af(\text{lld_af}, \text{LOCc}(\text{jaf}+n-1))$, $b(\text{lld_b}, \text{LOCc}(\text{jb}+\text{nrhs}-1))$, and $x(\text{lld_x}, \text{LOCc}(\text{jx}+\text{nrhs}-1))$, respectively. The array <i>a</i> contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. The array <i>af</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by <code>p?potrf</code> . On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$.

On entry, the array *x* contains the local pieces of the solution vectors *sub(X)*.

<i>ia, ja</i>	(global) INTEGER . The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) INTEGER . The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the matrix <i>sub(AF)</i> , respectively.
<i>descaf</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER . The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER . The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the matrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	<p>(local)</p> <p>REAL for <i>psporfs</i></p> <p>DOUBLE PRECISION for <i>pdporfs</i></p> <p>COMPLEX for <i>pcporfs</i></p> <p>DOUBLE COMPLEX for <i>pzporfs</i>.</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the array <i>work</i>.</p> <p>For real flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 3 * LOCr(n + \text{mod}(ia - 1, mb_a))$ <p>For complex flavors:</p> <p><i>lwork</i> must be at least</p> $lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb_a))$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$
<i>rwork</i>	(local) REAL for pcporfs DOUBLE PRECISION for pzporfs Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays of size $LOCc(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X). If XTRUE is the true solution corresponding to sub(X), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - \text{XTRUE})$ divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix X. The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork(1)</i>	On exit, <i>iwork(1)</i> contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork(1)</i>	On exit, <i>rwork(1)</i> contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. $info < 0$: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then $info = -(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$.

```

Include Files

Description

The `p?trrfs` routine provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$,

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$, or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$,

where $\text{sub}(A) = A(\text{ia}:\text{ia}+\text{n}-1, \text{ja}:\text{ja}+\text{n}-1)$ is a triangular matrix,

$\text{sub}(B) = B(\text{ib}:\text{ib}+\text{n}-1, \text{jb}:\text{jb}+\text{nrhs}-1)$, and

$\text{sub}(X) = X(\text{ix}:\text{ix}+\text{n}-1, \text{jx}:\text{jx}+\text{nrhs}-1)$.

The solution matrix X must be computed by `p?trtrs` or some other means before entering this routine. The routine `p?trrfs` does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be 'U' or 'L'. If <code>uplo</code> = 'U', $\text{sub}(A)$ is upper triangular. If <code>uplo</code> = 'L', $\text{sub}(A)$ is lower triangular.
<code>trans</code>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <code>trans</code> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose); If <code>trans</code> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).
<code>diag</code>	CHARACTER*1. Must be 'N' or 'U'. If <code>diag</code> = 'N', then $\text{sub}(A)$ is non-unit triangular.

If *diag* = 'U', then sub(A) is unit triangular.

<i>n</i>	(global) INTEGER. The order of the distributed matrix sub(A) ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, that is, the number of columns of the matrices sub(B) and sub(X) ($nrhs \geq 0$).
<i>a, b, x</i>	<p>(local)</p> <p>REAL for pstrrfs</p> <p>DOUBLE PRECISION for pdtrrfs</p> <p>COMPLEX for pctrfrfs</p> <p>DOUBLE COMPLEX for pztrrfs.</p> <p>Pointers into the local memory to arrays of local sizes $a(lld_a, LOCC(ja+n-1))$, $b(lld_b, LOCC(jb+nrhs-1))$, and $x(lld_x, LOCC(jx+nrhs-1))$, respectively.</p> <p>The array <i>a</i> contains the local pieces of the original triangular distributed matrix sub(A).</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(A) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(A) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.</p> <p>On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides sub(B).</p> <p>On entry, the array <i>x</i> contains the local pieces of the solution vectors sub(X).</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen</i> . The array descriptor for the distributed matrix A.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the matrix sub(B), respectively.
<i>descb</i>	(global and local) INTEGER array of size <i>dlen</i> . The array descriptor for the distributed matrix B.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global matrix X indicating the first row and the first column of the matrix sub(X), respectively.

<i>descx</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	<p>(local)</p> <p>REAL for pstrrfs</p> <p>DOUBLE PRECISION for pdtrrfs</p> <p>COMPLEX for pctrfs</p> <p>DOUBLE COMPLEX for pztrrfs.</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the array <i>work</i>.</p> <p>For real flavors:</p> <p><i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$</p> <p>For complex flavors:</p> <p><i>lwork</i> must be at least</p> <p>$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$</p>
<hr/> <p>NOTE</p> <p>$\text{mod}(x, y)$ is the integer remainder of x/y.</p> <hr/>	
<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	<p>(local or global) INTEGER. The size of the array <i>iwork</i>; used in real flavors only. Must be at least</p> <p>$liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.</p>
<i>rwork</i>	<p>(local) REAL for pctrfs</p> <p>DOUBLE PRECISION for pztrrfs</p> <p>Workspace array of size <i>lrwork</i>. Used in complex flavors only.</p>
<i>lrwork</i>	(local or global) INTEGER. The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

<i>ferr, berr</i>	<p>REAL for single precision flavors.</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Arrays of size $LOCc(jb + nrhs - 1)$ each.</p> <p>The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>X</i>).</p> <p>If XTRUE is the true solution corresponding to sub(<i>X</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(<i>X</i>) - XTRUE) divided by the magnitude of the largest element in sub(<i>X</i>). The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error.</p>
-------------------	--

This array is tied to the distributed matrix X .

The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix X .

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1)

On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1)

On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info

(global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Routines for Matrix Inversion

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

```
call psgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

```
call pdgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

```
call pcgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

```
call pzgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

Include Files

Description

The *p?getri* routine computes the inverse of a general distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the *LU* factorization computed by *p?getrf*. This method inverts *U* and then computes the inverse of $\text{sub}(A)$ by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for $\text{inv}(\text{sub}(A))$.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	<p>(local)</p> <p>REAL for psgetri</p> <p>DOUBLE PRECISION for pdgetri</p> <p>COMPLEX for pcgetri</p> <p>DOUBLE COMPLEX for pzgetri.</p> <p>Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$.</p> <p>On entry, the array <i>a</i> contains the local pieces of the <i>L</i> and <i>U</i> obtained by the factorization $sub(A) = P * L * U$ computed by p?getrf.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	<p>(local)</p> <p>REAL for psgetri</p> <p>DOUBLE PRECISION for pdgetri</p> <p>COMPLEX for pcgetri</p> <p>DOUBLE COMPLEX for pzgetri.</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the array <i>work</i>. <i>lwork</i> must be at least $lwork \geq LOCr(n + \text{mod}(ia - 1, mb_a)) * nb_a$.</p>
<hr/> <p>NOTE $\text{mod}(x, y)$ is the integer remainder of x/y.</p> <hr/>	
<p>The array <i>work</i> is used to keep at most an entire column block of sub(<i>A</i>).</p>	
<i>iwork</i>	(local) INTEGER. Workspace array used for physically transposing the pivots, size <i>liwork</i> .
<i>liwork</i>	(local or global) INTEGER. The size of the array <i>iwork</i> .

The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
  liwork = LOCC(n_a + mod(ja-1,nb_a)) + nb_a
else
  liwork = LOCC(n_a + mod(ja-1,nb_a)) +
  max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)),nb_a)
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

<i>ipiv</i>	<p>(local) INTEGER.</p> <p>Array of size $LOCr(m_a) + mb_a$.</p> <p>This array contains the pivoting information.</p> <p>If $ipiv(i)=j$, then the local row <i>i</i> was swapped with the global row <i>j</i>.</p> <p>This array is tied to the distributed matrix <i>A</i>.</p>
<i>work</i> (1)	<p>On exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.</p>
<i>iwork</i> (1)	<p>On exit, <i>iwork</i>(1) contains the minimum value of <i>liwork</i> required for optimum performance.</p>
<i>info</i>	<p>(global) INTEGER. If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> < 0:</p> <p>If the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then $info = -(i*100+j)$; if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.</p> <p><i>info</i> > 0:</p> <p>If $info = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, and division by zero will occur if it is used to solve a system of equations.</p>

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax

```
call pspotri(uplo, n, a, ia, ja, desca, info)
call pdpotri(uplo, n, a, ia, ja, desca, info)
call pcpotri(uplo, n, a, ia, ja, desca, info)
call pzpotri(uplo, n, a, ia, ja, desca, info)
```

Include Files

Description

The `p?potri` routine computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored. If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>pspotri</code> DOUBLE PRECISION for <code>pdpotri</code> COMPLEX for <code>pcpotri</code> DOUBLE COMPLEX for <code>pzpotri</code> . Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$. On entry, the array <i>a</i> contains the local pieces of the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by <code>p?potrf</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of $\text{sub}(A)$.
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0:

If $info = i$, the element (i, i) of the factor U or L is zero, and the inverse could not be computed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

```
call pstrtri(uplo, diag, n, a, ia, ja, desca, info)
call pdtrtri(uplo, diag, n, a, ia, ja, desca, info)
call pctrtri(uplo, diag, n, a, ia, ja, desca, info)
call pztrtri(uplo, diag, n, a, ia, ja, desca, info)
```

Include Files

Description

The `p?trtri` routine computes the inverse of a real or complex upper or lower triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. Specifies whether or not the distributed matrix $\text{sub}(A)$ is unit triangular. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>pstrtri</code> DOUBLE PRECISION for <code>pdtrtri</code> COMPLEX for <code>pctrtri</code> DOUBLE COMPLEX for <code>pztrtri</code> . Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$. The array <i>a</i> contains the local pieces of the triangular distributed matrix $\text{sub}(A)$.

If `uplo = 'U'`, the leading n -by- n upper triangular part of `sub(A)` contains the upper triangular matrix to be inverted, and the strictly lower triangular part of `sub(A)` is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of `sub(A)` contains the lower triangular matrix, and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja`

(global) `INTEGER`. The row and column indices in the global matrix `A` indicating the first row and the first column of the matrix `sub(A)`, respectively.

`desca`

(global and local) `INTEGER` array of size `dlen_`. The array descriptor for the distributed matrix `A`.

Output Parameters

`a`

On exit, overwritten by the (triangular) inverse of the original matrix.

`info`

(global) `INTEGER`. If `info=0`, the execution is successful.

`info < 0`:

If the i -th argument is an array and the j -th entry had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

`info > 0`:

If `info = k`, `A(ia+k-1, ja+k-1)` is exactly zero. The triangular matrix `sub(A)` is singular and its inverse cannot be computed.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

Routines for Matrix Equilibration

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

```
call psgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

```
call pdgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

```
call pcgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

```
call pzgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

Include Files

Description

The `p?geequ` routine computes row and column scalings intended to equilibrate an m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors r_i , and the array c returns the column scale factors c_j . These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r_i*a_{ij}*c_j$ have absolute value 1.

r_i and c_j are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $\text{sub}(A)$ but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

The auxiliary function `p?laqge` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>psgeequ</code> DOUBLE PRECISION for <code>pdgeequ</code> COMPLEX for <code>pcgeequ</code> DOUBLE COMPLEX for <code>pzgeequ</code> . Pointer into the local memory to an array of local size $(lld_a, LOCC(ja+n-1))$. The array a contains the local pieces of the m -by- n distributed matrix whose equilibration factors are to be computed.
ia, ja	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

Output Parameters

r, c	(local) REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Arrays of sizes $LOCr(m_a)$ and $LOCC(n_a)$, respectively.
--------	---

If $info = 0$, or $info > ia+m-1$, the array $r(ia:ia+m-1)$ contains the row scale factors for $sub(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A .

If $info = 0$, the array $c(ja:ja+n-1)$ contains the column scale factors for $sub(A)$. c is aligned with the distributed matrix A , and replicated down every process row. c is tied to the distributed matrix A .

rowcnd, colcnd

(global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

If $info = 0$ or $info > ia+m-1$, *rowcnd* contains the ratio of the smallest $r(i)$ to the largest $r(i)$ ($ia \leq i \leq ia+m-1$). If $rowcnd \geq 0.1$ and *amax* is neither too large nor too small, it is not worth scaling by $r(ia:ia+m-1)$.

If $info = 0$, *colcnd* contains the ratio of the smallest $c(j)$ to the largest $c(j)$ ($ja \leq j \leq ja+n-1$).

If $colcnd \geq 0.1$, it is not worth scaling by $c(ja:ja+n-1)$.

amax

(global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

info

(global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = i$ and

$i \leq m$, the i -th row of the distributed matrix

$sub(A)$ is exactly zero;

$i > m$, the $(i - m)$ -th column of the distributed

matrix $sub(A)$ is exactly zero.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

call pspoequ(*n, a, ia, ja, desca, sr, sc, scond, amax, info*)

call pdpoequ(*n, a, ia, ja, desca, sr, sc, scond, amax, info*)

call pcpcpoequ(*n, a, ia, ja, desca, sr, sc, scond, amax, info*)

```
call pzpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
```

Include Files

Description

The `p?poequ` routine computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ and reduce its condition number (with respect to the two-norm). The output arrays `sr` and `sc` return the row and column scale factors

, ! ! ! ! ! ! ! !

These factors are chosen so that the scaled distributed matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has ones on the diagonal.

This choice of `sr` and `sc` puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

<code>n</code>	(global) INTEGER . The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pspoequ</code> DOUBLE PRECISION for <code>pdpoequ</code> COMPLEX for <code>pcpoequ</code> DOUBLE COMPLEX for <code>pzpoequ</code> . Pointer into the local memory to an array of local size $(lld_a, LOCC(ja+n-1))$. The array <code>a</code> contains the n -by- n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.
<code>ia, ja</code>	(global) INTEGER . The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

Output Parameters

<code>sr, sc</code>	(local) REAL for single precision flavors;
---------------------	--

DOUBLE PRECISION for double precision flavors.

Arrays of sizes $LOCr(m_a)$ and $LOCc(n_a)$, respectively.

If $info = 0$, the array $sr(ia:ia+n-1)$ contains the row scale factors for $sub(A)$. sr is aligned with the distributed matrix A , and replicated across every process column. sr is tied to the distributed matrix A .

If $info = 0$, the array $sc(ja:ja+n-1)$ contains the column scale factors for $sub(A)$. sc is aligned with the distributed matrix A , and replicated down every process row. sc is tied to the distributed matrix A .

scond

(global)

REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

If $info = 0$, *scond* contains the ratio of the smallest $sr(i)$ (or $sc(j)$) to the largest $sr(i)$ (or $sc(j)$), with

$ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.

If $scond \geq 0.1$ and *amax* is neither too large nor too small, it is not worth scaling by sr (or sc).

amax

(global)

REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.

Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

info

(global) INTEGER.

If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, the k -th diagonal entry of $sub(A)$ is nonpositive.

[p?geqrf](#)

Computes the QR factorization of a general m -by- n matrix.

Syntax

```
call psgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqrf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files**Description**

The `p?geqrf` routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$A = Q * R$.

Input Parameters

m (global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$; ($m \geq 0$).

n (global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$; ($n \geq 0$).

<i>a</i>	<p>(local)</p> <p>REAL for psgeqrf</p> <p>DOUBLE PRECISION for pdgeqrf</p> <p>COMPLEX for pcgeqrf</p> <p>DOUBLE COMPLEX for pzgeqrf.</p> <p>Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$.</p> <p>Contains the local pieces of the distributed matrix sub(A) to be factored.</p>

<i>tau</i>	<p>(local)</p>

REAL for psgeqrf

DOUBLE PRECISION for pdgeqrf

COMPLEX for pcgeqrf

DOUBLE COMPLEX for pzgeqrf.

Array of size $LOCc(ja+\min(m,n)-1)$.

Contains the scalar factor of elementary reflectors. τ is tied to the distributed matrix A .

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0, the execution is successful.

< 0, if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja)*H(ja+1)*...*H(ja+k-1),$$

where $k = \min(m,n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

p?geqpf

Computes the QR factorization of a general m-by-n matrix with pivoting.

Syntax

```
call psgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
```

```
call pdgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
```

```
call pcgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, rwork, lrwork, info)
```

```
call pzgeqpf(m, n, a, ia, ja, desca, ipiv, tau, work, lwork, rwork, lrwork, info)
```

Include Files

Description

The `p?geqpf` routine forms the QR factorization with column pivoting of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$\text{sub}(A)*P=Q*R.$$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix sub(<i>A</i>) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf. Pointer into the local memory to an array of local size (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> - 1)). Contains the local pieces of the distributed matrix sub(<i>A</i>) to be factored.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> (<i>ia</i> : <i>ia</i> + <i>m</i> -1, <i>ja</i> : <i>ja</i> + <i>n</i> -1), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgeqpf DOUBLE PRECISION for pdgeqpf. COMPLEX for pcgeqpf. DOUBLE COMPLEX for pzgeqpf Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least For real flavors: $lwork \geq \max(3, mp0 + nq0) + LOCc(ja + n - 1) + nq0$. For complex flavors: $lwork \geq \max(3, mp0 + nq0)$. Here $iroff = \text{mod}(ia - 1, mb_a)$, $icoff = \text{mod}(ja - 1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mp0 = \text{numroc}(m + iroff, mb_a, MYROW, iarow, NPROW)$, $nq0 = \text{numroc}(n + icoff, nb_a, MYCOL, iacol, NPCOL)$, $LOCc(ja + n - 1) = \text{numroc}(ja + n - 1, nb_a, MYCOL, csrc_a, NPCOL)$, and <i>numroc</i> , <i>indxg2p</i> are ScaLAPACK tool functions. You can determine MYROW, MYCOL, NPROW and NPCOL by calling the <i>blacs_gridinfo</i> subroutine.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

$rwork$

(local).

REAL for pcgeqpf.

DOUBLE PRECISION for pzgeqpf.

Workspace array of size $lrwork$ (complex flavors only).

$lrwork$

(local or global) INTEGER, size of $rwork$ (complex flavors only). The value of $lrwork$ must be at least

$lwork \geq LOCC(ja+n-1) + nq0$.

Here

$iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,
 $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,
 $mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW)$,
 $nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$,
 $LOCC(ja+n-1) = \text{numroc}(ja+n-1, nb_a, MYCOL, csrc_a, NPCOL)$,
 and numroc , indxg2p are ScaLAPACK tool functions.

You can determine MYROW, MYCOL, NPROW and NPCOL by calling the `blacs_gridinfo` subroutine.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

$ipiv$

(local) INTEGER. Array of size $LOCC(ja+n-1)$.

$ipiv(i) = k$, the local i -th column of $\text{sub}(A)*P$ was the global k -th column of $\text{sub}(A)$. $ipiv$ is tied to the distributed matrix A .

τ

(local)

REAL for psgeqpf

DOUBLE PRECISION for pdgeqpf

COMPLEX for pcgeqpf

DOUBLE COMPLEX for pzgeqpf.

	Array of size $LOCc(ja+\min(m, n)-1)$.
	Contains the scalar factor τ of elementary reflectors. τ is tied to the distributed matrix A .
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$rwork(1)$	On exit, $rwork(1)$ contains the minimum value of $lrwork$ required for optimum performance.
$info$	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*...*H(k)$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$.

The matrix P is represented in $ipiv$ as follows: if $ipiv(j) = i$ then the j -th column of P is the i -th canonical unit vector.

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call psorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pdorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The p?orgqrroutine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1)*H(2)*...*H(k)$$

as returned by p?geqrf.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psorgqr DOUBLE PRECISION for pdorgqr Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$. The j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja + k - 1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) REAL for psorgqr DOUBLE PRECISION for pdorgqr Array of size $LOCC(ja+k-1)$. Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqrf . τ is tied to the distributed matrix A .
<i>work</i>	(local) REAL for psorgqr DOUBLE PRECISION for pdorgqr Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> . Must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW)$, $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$; indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code> .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a	Contains the local pieces of the m -by- n distributed matrix Q .
$work(1)$	On exit, (1) contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by [p?geqrf](#).

Syntax

```
call pcungqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1)*H(2)*...*H(k)$$

as returned by [p?geqrf](#).

Input Parameters

m	(global) INTEGER. The number of rows in the matrix sub(Q); ($m \geq 0$).
n	(global) INTEGER. The number of columns in the matrix sub(Q) ($m \geq n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) COMPLEX for pcungqr DOUBLE COMPLEX for pzungqr

Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. The j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by [p?geqrf](#) in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

tau

(local)

COMPLEX for [pcungqr](#)

DOUBLE COMPLEX for [pzungqr](#)

Array of size $LOCC(ja+k-1)$.

Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by [p?geqrf](#). τ is tied to the distributed matrix A .

work

(local)

COMPLEX for [pcungqr](#)

DOUBLE COMPLEX for [pzungqr](#)

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where

$iroffa = \text{mod}(ia-1, mb_a)$,

$icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW)$,

$nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$

[indxg2p](#) and [numroc](#) are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine [blacs_gridinfo](#).

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

Contains the local pieces of the m -by- n distributed matrix Q .

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call psormqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormqr(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

The p?ormqr routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by p?geqrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = 'L' : Q or Q^T is applied from the left. = 'R' : Q or Q^T is applied from the right.
$trans$	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i>. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCc(ja+n-1))$. <i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr</p> <p>Array of size $LOCc(ja+k-1)$.</p> <p>Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqrf. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr</p> <p>Pointer into the local memory to an array of local size $(lld_c, LOCc(jc+n-1))$.</p> <p>Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the matrix sub(<i>C</i>), respectively.</p>
<i>descc</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>C</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr.</p>

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

if *side* = 'L',

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$

else if *side* = 'R',

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$

end if

where

$lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,

$iroffa = \text{mod}(ia - 1, mb_a)$,

$icoffa = \text{mod}(ja - 1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

$npa0 = \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW)$,

$iroffc = \text{mod}(ic - 1, mb_c)$,

$icoffc = \text{mod}(jc - 1, nb_c)$,

$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,

$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,

$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,

$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pserbla*.

Output Parameters

c

Overwritten by the product $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C)$, or $\text{sub}(C) * Q^T$, or $\text{sub}(C) * Q$.

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by [p?geqrf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
a	(local) COMPLEX for pcunmqr

	DOUBLE COMPLEX for pzunmqr.
	Pointer into the local memory to an array of size $(lld_a, LOCc(ja+k-1))$. The j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.
	If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$
	If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr Array of size $LOCc(ja+k-1)$. Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqrf . τ is tied to the distributed matrix A .
<i>c</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr. Pointer into the local memory to an array of local size $(lld_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub(C) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>descc</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix C .
<i>work</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr. Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least: If $side = 'L'$, $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$ else if $side = 'R'$,

```

lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0 +
numroc(numroc(n+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0,
lcmq), mpc0))*nb_a) + nb_a*nb_a

```

end if

where

```

lcmq = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the subroutine
blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c	Overwritten by the product $Q*\text{sub}(C)$, or $Q^H*\text{sub}(C)$, or $\text{sub}(C)*Q^H$, or $\text{sub}(C)*Q$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?gelqf

Computes the LQ factorization of a general rectangular matrix.

Syntax

```
call psgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelqf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The `p?gelqf` routine computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>psgelqf</code> DOUBLE PRECISION for <code>pdgelqf</code> COMPLEX for <code>pcgelqf</code> DOUBLE COMPLEX for <code>pzgelqf</code> Pointer into the local memory to an array of local size $(l1d_a, LOCC(ja + n - 1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $A(ia:ia + m - 1, ja:ja + n - 1)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size $d/en_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local) REAL for <code>psgelqf</code> DOUBLE PRECISION for <code>pdgelqf</code> COMPLEX for <code>pcgelqf</code> DOUBLE COMPLEX for <code>pzgelqf</code> Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia - 1, mb_a)$,

```

icoff = mod(ja-1, nb_a),
iarow = indxcg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxcg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)

```

`indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

NOTE

`mod(x, y)` is the integer remainder of x/y .

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	The elements on and below the diagonal of sub(A) contain the m -by- $\min(m, n)$ lower trapezoidal matrix L (L is lower trapezoidal if $m \leq n$); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Array of size $LOCr(ia+\min(m, n)-1)$. Contains the scalar factors of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <code>lwork</code> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1)*H(ia+k-2)*\dots*H(ia),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and τ in $\tau(ia+i-1)$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call psorglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The p?orglq routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?gelqf.

Input Parameters

m	(global) INTEGER. The number of rows in the matrix sub(Q); ($m \geq 0$).
n	(global) INTEGER. The number of columns in the matrix sub(Q) ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Pointer into the local memory to an array of local size $(lld_a, LOCC(ja+n-1))$. On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
ia, ja	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

work (local)
 REAL for psorglq
 DOUBLE PRECISION for pdorglq
 Workspace array of size of *lwork*.

lwork (local or global) INTEGER, size of *work*, must be at least
 $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where

```

irowfa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+irowfa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a Contains the local pieces of the m -by- n distributed matrix Q to be factored.

tau (local)
 REAL for psorglq
 DOUBLE PRECISION for pdorglq
 Array of size $LOCr(ia+k-1)$.
 Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. *tau* is tied to the distributed matrix A .

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

See Also

p?unglq

Generates the unitary matrix Q of the LQ factorization formed by `p?gelqf`.

Syntax

```
call pcunglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzunglq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?gelqf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix sub(Q) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix sub(Q) ($n \geq m \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Pointer into the local memory to an array of local size $(lld_a, LOcc(ja+n-1))$. On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Array of size $LOCr(ia+k-1)$. Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. τ is tied to the distributed matrix A .
<i>work</i>	(local) COMPLEX for <code>pcunglq</code>

DOUBLE COMPLEX for pzunglq

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least

$lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where

$iroffa = \text{mod}(ia-1, mb_a)$,

$icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW)$,

$nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$

indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

Contains the local pieces of the *m*-by-*n* distributed matrix *Q* to be factored.

work(1)

On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?ormlq

Multiplies a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

call psormlq(*side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work, lwork, info*)

call pdormlq(*side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work, lwork, info*)

Include Files

Description

The `p?ormlq` routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> . Pointer into the local memory to an array of size $(lld_a, LOCC(ja+m-1))$, if $side = 'L'$ and $(lld_a, LOCC(ja+n-1))$, if $side = 'R'$. The i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
ia, ja	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq Array of size <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau(j)</i> of elementary reflectors <i>H(j)</i> as returned by p?gelqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq Pointer into the local memory to an array of local size <i>(lld_c, LOCc(jc+n-1))</i> . Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormlq DOUBLE PRECISION for pdormlq. Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of the array <i>work</i> ; must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0)) * mb_a) + mb_a * mb_a$ else if <i>side</i> = 'R', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a)$ end if where $lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$, $iroffc = \text{mod}(ic - 1, mb_c)$,

```

icoffc = mod(jc-1, nb_c),
icrow = indxcg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxcg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

call pzunmlq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

```

Include Files

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<i>trans</i> = 'T':	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?gelqf](#). Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq. Pointer into the local memory to an array of size $(ll_d_a, LOCC(ja+m-1))$, if <i>side</i> = 'L' and $(ll_d_a, LOCC(ja+n-1))$, if <i>side</i> = 'R', where $ll_d_a \geq \max(1, LOCr(ia+k-1))$. The i -th column must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq

Array of size $LOCc(ia+k-1)$.

Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by `p?gelqf`. τ is tied to the distributed matrix A .

c

(local)

COMPLEX for `pcunmlq`

DOUBLE COMPLEX for `pzunmlq`.

Pointer into the local memory to an array of local size $(lld_c, LOCc(jc+n-1))$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

ic, jc

(global) INTEGER. The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

desc

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix C .

work

(local)

COMPLEX for `pcunmlq`

DOUBLE COMPLEX for `pzunmlq`.

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of the array *work*; must be at least:

If *side* = 'L',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + maxmqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0) * mb_a) + mb_a * mb_a$$

else if *side* = 'R',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a$$

end if

where

$lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,

$iroffa = \text{mod}(ia-1, mb_a)$,

$icoffa = \text{mod}(ja-1, nb_a)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$,

$iroffc = \text{mod}(ic-1, mb_c)$,

$icoffc = \text{mod}(jc-1, nb_c)$,

$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,

$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,

$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,

$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?geqlf

Computes the QL factorization of a general matrix.

Syntax

```
call psgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files**Description**

The `p?geqlf` routine forms the QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1) = Q \cdot L$.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows in the matrix $\text{sub}(Q)$; ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the matrix $\text{sub}(Q)$ ($n \geq 0$).

<i>a</i>	<p>(local)</p> <p>REAL for psgeqlf</p> <p>DOUBLE PRECISION for pdgeqlf</p> <p>COMPLEX for pcgeqlf</p> <p>DOUBLE COMPLEX for pzgeqlf</p> <p>Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$. Contains the local pieces of the distributed matrix sub(A) to be factored.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix A.</p>
<i>work</i>	<p>(local)</p> <p>REAL for psgeqlf</p> <p>DOUBLE PRECISION for pdgeqlf</p> <p>COMPLEX for pcgeqlf</p> <p>DOUBLE COMPLEX for pzgeqlf</p> <p>Workspace array of size of <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, size of <i>work</i>, must be at least $lwork \geq nb_a * (mp0 + nq0 + nb_a)$, where</p> <p>$iroff = \text{mod}(ia-1, mb_a)$,</p> <p>$icoff = \text{mod}(ja-1, nb_a)$,</p> <p>$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,</p> <p>$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,</p> <p>$mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW)$,</p> <p>$nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$</p>

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`numroc` and `indxg2p` are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Array of size $LOCc(ja+n-1)$. Contains the scalar factors of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1)*\dots*H(ja+1)*H(ja)$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau(ja+n-k+i-1)$.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call psorgql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pdorgql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The `p?orgql` routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by `p?geqlf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix sub(Q), ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix sub(Q), ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Pointer into the local memory to an array of local size $(lld_a, LOCC(ja+n-1))$. On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its distributed matrix argument $A(ia:*, ja+n-k:ja+n-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Array of size $LOCC(ja+n-1)$. Contains the scalar factors $tau(j)$ of elementary reflectors $H(j)$. tau is tied to the distributed matrix A .
<i>work</i>	(local) REAL for <code>psorgql</code> DOUBLE PRECISION for <code>pdorgql</code> Workspace array of size of $lwork$.
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$,

```

icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ungql

Generates the unitary matrix Q of the QL factorization formed by `p?geqlf`.

Syntax

```

call pcungql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungql(m, n, k, a, ia, ja, desca, tau, work, lwork, info)

```

Include Files**Description**

This routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first n columns of a product of k elementary reflectors of order m

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?geqlf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix sub(<i>Q</i>) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix sub(<i>Q</i>) ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> ($n \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Pointer into the local memory to an array of local size (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)). On entry, the <i>j</i> -th column must contain the vector that defines the elementary reflector <i>H</i> (<i>j</i>), $ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument <i>A</i> (<i>ia</i> *, <i>ja</i> + <i>n</i> - <i>k</i> : <i>ja</i> + <i>n</i> -1).
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> (<i>ia</i> : <i>ia</i> + <i>m</i> -1, <i>ja</i> : <i>ja</i> + <i>n</i> -1), respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Array of size <i>LOCr</i> (<i>ia</i> + <i>n</i> -1). Contains the scalar factors <i>tau</i> (<i>j</i>) of elementary reflectors <i>H</i> (<i>j</i>). <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

a	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ormql

Multiplies a general matrix by the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call psormql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

The `p?ormql` routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^T is applied from the left.
--------	---

= 'R' : Q or Q^T is applied from the right.

trans

(global) CHARACTER

= 'N' , no transpose, Q is applied.

= 'T' , transpose, Q^T is applied.

m

(global) INTEGER. The number of rows in the distributed matrix sub(C), ($m \geq 0$).

n

(global) INTEGER. The number of columns in the distributed matrix sub(C), ($n \geq 0$).

k

(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

If *side* = 'L', $m \geq k \geq 0$

If *side* = 'R', $n \geq k \geq 0$.

a

(local)

REAL for psormql

DOUBLE PRECISION for pdormql.

Pointer into the local memory to an array of size $(lld_a, LOCc(ja+k-1))$. The j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?ge1qf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.

If *side* = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$,

If *side* = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

tau

(local)

REAL for psormql

DOUBLE PRECISION for pdormql.

Array of size $LOCc(ja+n-1)$.

Contains the scalar factor $\tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqlf. τ is tied to the distributed matrix A .

c

(local)

REAL for psormql

DOUBLE PRECISION for pdormql.

Pointer into the local memory to an array of local size $(lld_c, LOCc(jc+n-1))$.

	Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psormql DOUBLE PRECISION for pdormql. Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$ else if <i>side</i> = 'R', $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + iroffa, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a + nb_a * nb_a)$ end if where $lcmq = lcm / NPCOL \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia - 1, mb_a),$ $icoffa = \text{mod}(ja - 1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $npa0 = \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW),$ $iroffc = \text{mod}(ic - 1, mb_c),$ $icoffc = \text{mod}(jc - 1, nb_c),$ $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW),$ $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL),$ $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW),$ $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL),$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

c	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmql

Multiplies a general matrix by the unitary matrix Q of the QL factorization formed by `p?geqlf`.

Syntax

```
call pcunmql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmql(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

This routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q^* \text{sub}(C)$	$\text{sub}(C)^* Q$
$trans = 'C':$	$Q^H \text{sub}(C)$	$\text{sub}(C)^* Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^H is applied from the left.
--------	---

	= 'R': Q or Q^H is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(C) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(C) ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmql DOUBLE COMPLEX for pzunmql. Pointer into the local memory to an array of size $(lld_a, LOCC(ja+k-1))$. ```

Include Files**Description**

The `p?gerqf` routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = R^*Q$$

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$; ($m \geq 0$).
----------------	--

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(A); ($n \geq 0$).
<i>a</i>	<p>(local)</p> <p>REAL for psgeqrf</p> <p>DOUBLE PRECISION for pdgeqrf</p> <p>COMPLEX for pcgeqrf</p> <p>DOUBLE COMPLEX for pzgeqrf.</p> <p>Pointer into the local memory to an array of local size $(lld_a, LOCC(ja + n - 1))$.</p> <p>Contains the local pieces of the distributed matrix sub(A) to be factored.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix A
<i>work</i>	<p>(local).</p> <p>REAL for psgeqrf</p> <p>DOUBLE PRECISION for pdgeqrf.</p> <p>COMPLEX for pcgeqrf.</p> <p>DOUBLE COMPLEX for pzgeqrf</p> <p>Workspace array of size <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) INTEGER, size of <i>work</i>, must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where</p> <p>$iroff = \text{mod}(ia - 1, mb_a)$,</p> <p>$icoff = \text{mod}(ja - 1, nb_a)$,</p> <p>$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,</p> <p>$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,</p> <p>$mp0 = \text{numroc}(m + iroff, mb_a, MYROW, iarow, NPROW)$,</p>

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$nq0 = \text{numroc}(n + icoff, nb_a, MYCOL, iacol, NPCOL)$ and numroc , indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Array of size $LOCr(ia+m-1)$. Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $\tau(ia+m-k+i-1)$.

p?orgrq

Generates the orthogonal matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call psorgrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

```
call pdorgrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The `p?orgqr` routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows that is defined as the last m rows of a product of k elementary reflectors of order n

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?gerqf`.

Input Parameters

m	(global) INTEGER. The number of rows in the matrix sub(Q), ($m \geq 0$).
n	(global) INTEGER. The number of columns in the matrix sub(Q), ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Pointer into the local memory to an array of local size $(lld_a, LOCC(ja+n-1))$. The i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+m-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
ia, ja	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
tau	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gerqf</code> . tau is tied to the distributed matrix A .
$work$	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Workspace array of size of $lwork$.
$lwork$	(local or global) INTEGER, size of $work$, must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$,

```

icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

NOTE

`mod(x, y)` is the integer remainder of x/y .

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ungrq

Generates the unitary matrix Q of the RQ factorization formed by `p?gerqf`.

Syntax

```

call pcungrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungrq(m, n, k, a, ia, ja, desca, tau, work, lwork, info)

```

Include Files**Description**

This routine generates the m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by `p?gerqf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the matrix sub(<i>Q</i>); ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the matrix sub(<i>Q</i>) ($n \geq m \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> ($m \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrqc Pointer into the local memory to an array of size $(lld_a, LOCc(ja+n-1))$. The <i>i</i> -th row must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Array of size $LOCr(ia+m-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrq Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q .
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ormrq

Multiplies a general matrix by the orthogonal matrix Q of the RQ factorization formed by `p?gerqf`.

Syntax

```
call psormrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormrq(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files**Description**

The `p?ormrq` routine overwrites the general real m -by- n distributed matrix sub $(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	<p>(global) CHARACTER</p> <p>= 'L': Q or Q^T is applied from the left.</p> <p>= 'R': Q or Q^T is applied from the right.</p>
<i>trans</i>	<p>(global) CHARACTER</p> <p>= 'N', no transpose, Q is applied.</p> <p>= 'T', transpose, Q^T is applied.</p>
<i>m</i>	<p>(global) INTEGER. The number of rows in the distributed matrix sub(C)</p> <p>($m \geq 0$).</p>
<i>n</i>	<p>(global) INTEGER. The number of columns in the distributed matrix sub(C)</p> <p>($n \geq 0$).</p>
<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCC(ja+m-1))$ if <i>side</i> = 'L', and $(lld_a, LOCC(ja+n-1))$ if <i>side</i> = 'R'.</p> <p>The <i>i</i>-th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq j \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psormqr</p> <p>DOUBLE PRECISION for pdormqr</p> <p>Array of size $LOCC(ja+k-1)$.</p> <p>Contains the scalar factor $tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix A.</p>
<i>c</i>	<p>(local)</p> <p>REAL for psormqr</p>

DOUBLE PRECISION for `pdormrq`

Pointer into the local memory to an array of local size $(lld_c, LOCC(jc + n - 1))$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

ic, jc

(global) INTEGER. The row and column indices in the global matrix C indicating the first row and the first column of the matrix $\text{sub}(C)$, respectively.

descc

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix C .

work

(local)

REAL for `psormrq`

DOUBLE PRECISION for `pdormrq`.

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

If *side* = 'L',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0)) * mb_a) + mb_a * mb_a)$$

else if *side* = 'R',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$$

end if

where

$lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,

$iroffa = \text{mod}(ia - 1, mb_a)$,

$icoffa = \text{mod}(ja - 1, nb_a)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$,

$iroffc = \text{mod}(ic - 1, mb_c)$,

$icoffc = \text{mod}(jc - 1, nb_c)$,

$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,

$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,

$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,

$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?tzrzf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

```
call pstzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdtzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pctzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pztzrzf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The `p?tzrzf` routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = (R \ 0)^* Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows in the matrix $\text{sub}(A)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>pstzrzf</code>

DOUBLE PRECISION for pdtzrzf.

COMPLEX for pctzrzf.

DOUBLE COMPLEX for pztzrzf.

Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix sub (A) to be factored.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

work

(local)

REAL for pstzrzf

DOUBLE PRECISION for pdtzrzf.

COMPLEX for pctzrzf.

DOUBLE COMPLEX for pztzrzf.

Workspace array of size of *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least

$lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where

$iroff = \text{mod}(ia-1, mb_a)$,

$icoff = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mp0 = \text{numroc}(m + iroff, mb_a, MYROW, iarow, NPROW)$,

$nq0 = \text{numroc}(n + icoff, nb_a, MYCOL, iacol, NPCOL)$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the leading m -by- m upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix R , and elements $m+1$ to n of the first m rows of $\text{sub}(A)$, with the array <i>tau</i> , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>tau</i>	(local) REAL for pstzrzf DOUBLE PRECISION for pdtzrzf. COMPLEX for pctzrzf. DOUBLE COMPLEX for pztzrzf. Array of size $LOCr(ia+m-1)$. Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$\begin{pmatrix} 1 & & & & & & & \\ & \ddots & & & & & & \\ & & \ddots & & & & & \\ & & & \ddots & & & & \\ & & & & \tau & & & \\ & & & & & \ddots & & \\ & & & & & & \ddots & \\ & & & & & & & 1 \end{pmatrix}$$

where

$$T(k) = I - \tau u(k) u(k)',$$

$$\begin{pmatrix} 1 & & & & & & & \\ & \ddots & & & & & & \\ & & \ddots & & & & & \\ & & & \ddots & & & & \\ & & & & \tau & & & \\ & & & & & \ddots & & \\ & & & & & & \ddots & \\ & & & & & & & 1 \end{pmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$. Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

p?ormrz

Multiplies a general matrix by the orthogonal matrix from a reduction to upper triangular form formed by p?tzzrf.

Syntax

```
call psormrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

This routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by [p?tzzrf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = $'L'$: Q or Q^T is applied from the left. = $'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER = $'N'$, no transpose, Q is applied. = $'T'$, transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

<i>k</i>	<p>(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i>. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p>
<i>l</i>	<p>(global)</p> <p>The columns of the distributed matrix sub(<i>A</i>) containing the meaningful part of the Householder reflectors.</p> <p>If <i>side</i> = 'L', $m \geq l \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq l \geq 0$.</p>
<i>a</i>	<p>(local)</p> <p>REAL for psormrz</p> <p>DOUBLE PRECISION for pdormrz.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCc(ja+m-1))$ if <i>side</i> = 'L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R', where $lld_a \geq \max(1, LOCr(ia+k-1))$.</p> <p>The <i>i</i>-th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq j \leq ia+k-1$, as returned by p?tzrzf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p>
<i>tau</i>	<p>(local)</p> <p>REAL for psormrz</p> <p>DOUBLE PRECISION for pdormrz</p> <p>Array of size $LOCc(ia+k-1)$.</p> <p>Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?tzrzf. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local)</p> <p>REAL for psormrz</p> <p>DOUBLE PRECISION for pdormrz</p> <p>Pointer into the local memory to an array of local size $(lld_c, LOCc(jc+n-1))$.</p> <p>Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.</p>

<i>desc</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for <i>psormrz</i> DOUBLE PRECISION for <i>pdormrz</i> . Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0)) * mb_a) + mb_a * mb_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$ end if where $lcm = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$, $iroffc = \text{mod}(ic - 1, mb_c)$, $icoffc = \text{mod}(jc - 1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$, $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$, $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$, $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$
----------	---

<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?unmrz

Multiplies a general matrix by the unitary transformation matrix from a reduction to upper triangular form determined by p?tzrzf.

Syntax

```
call pcunmrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmrz(side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

This routine overwrites the general complex m -by- n distributed matrix sub (C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `pctzrzf/pztzrzf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<code>side</code>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<code>trans</code>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(C), ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(C), ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>l</i>	(global) INTEGER. The columns of the distributed matrix sub(A) containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ If <i>side</i> = 'R', $n \geq l \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of size (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>m</i> -1)) if <i>side</i> = 'L', and (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)) if <i>side</i> = 'R', where $lld_a \geq \max(1, LOCr(ja+k-1))$. The <i>i</i> -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix A.
<i>tau</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz Array of size <i>LOCc</i> (<i>ia</i> + <i>k</i> -1). Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf . <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of local size (<i>lld_c</i> , <i>LOCc</i> (<i>jc</i> + <i>n</i> -1)). Contains the local pieces of the distributed matrix sub(C) to be factored.

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0)) * mb_a) + mb_a * mb_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$ end if where $lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia - 1, mb_a),$ $icoffa = \text{mod}(ja - 1, nb_a),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL),$ $iroffc = \text{mod}(ic - 1, mb_c),$ $icoffc = \text{mod}(jc - 1, nb_c),$ $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW),$ $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL),$ $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW),$ $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL),$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ggqrf

Computes the generalized QR factorization.

Syntax

```
call psggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work, lwork, info)
```

```
call pdggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work, lwork, info)
```

```
call pcggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work, lwork, info)
```

```
call pzggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work, lwork, info)
```

Include Files

Description

The `p?ggqrf` routine forms the generalized QR factorization of an n -by- m matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$

and an n -by- p matrix

$\text{sub}(B) = B(ib:ib+n-1, jb:jb+p-1)$:

as

$\text{sub}(A) = Q^* R$, $\text{sub}(B) = Q^* T^* Z$,

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

If $n \geq m$

$$R = \begin{pmatrix} R_{11} & & \\ & 0 & \\ & & \end{pmatrix} \begin{matrix} m \\ n - m \\ m \end{matrix}$$

or if $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} n \\ n & m - n \end{matrix}$$

where R_{11} is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n & n \end{matrix}$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n - p \\ p \end{pmatrix}, \text{ if } n > p,$$

p

where T_{12} or T_{21} is an upper triangular matrix.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GQR factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the QR factorization of $\text{inv}(\text{sub}(B)) * \text{sub}(A)$:

$$\text{inv}(\text{sub}(B)) * \text{sub}(A) = Z^H * (\text{inv}(T) * R)$$

Input Parameters

n	(global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
m	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
p	INTEGER. The number of columns in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
a	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf.

	Pointer into the local memory to an array of size $(lld_a, LOcc(ja+m-1))$. Contains the local pieces of the n -by- m matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Pointer into the local memory to an array of size $(lld_b, LOcc(jb+p-1))$. Contains the local pieces of the n -by- p matrix $\text{sub}(B)$ to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.
<i>descb</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .
<i>work</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of <i>work</i> , must be at least $lwork \geq \max(nb_a * (npa0 + mqa0 + nb_a), \max((nb_a * (nb_a - 1)) / 2, (pqb0 + npb0) * nb_a + nb_a * nb_a, mb_b * (npb0 + pqb0 + mb_b))),$ where $iroffa = \text{mod}(ia - 1, mb_A),$ $icoffa = \text{mod}(ja - 1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $npa0 = \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW),$ $mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$ $iroffb = \text{mod}(ib - 1, mb_b),$ $icoffb = \text{mod}(jb - 1, nb_b),$ $ibrow = \text{indxg2p}(ib, mb_b, MYROW, rsrc_b, NPROW),$

```

ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc (n+iroffa, mb_b, MYROW, Ibrow, NPROW),
pqb0 = numroc(m+icoffb, nb_b, MYCOL, ibcol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, the elements on and above the diagonal of sub (*A*) contain the $\min(n, m)$ -by- m upper trapezoidal matrix *R* (*R* is upper triangular if $n \geq m$); the elements below the diagonal, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of $\min(n, m)$ elementary reflectors. (See Application Notes below).

taua, taub

(local)

REAL for psggqrf

DOUBLE PRECISION for pdggqrf

COMPLEX for pcggqrf

DOUBLE COMPLEX for pzggqrf.

Arrays of size $LOC(ja + \min(n, m) - 1)$ for *taua* and $LOC(ib + n - 1)$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *taua* is tied to the distributed matrix *A*. (See Application Notes below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See Application Notes below).

work(1)

On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(j_a) * H(j_a+1) * \dots * H(j_a+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_a v v'$$

where τ_a is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ_a in $\tau_a(ja+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(ib) * H(ib+1) * \dots * H(ib+k-1), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_b v v'$$

where τ_b is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and τ_b in $\tau_b(ib+n-k+i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

Description

The [p?ggrqf](#) routine forms the generalized RQ factorization of an m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and a p -by- n matrix $\text{sub}(B) = B(ib:ib+p-1, jb:jb+n-1)$:

$$\text{sub}(A) = R * Q, \text{ sub}(B) = Z * T * Q,$$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{pmatrix} 0 & R_{12} \\ R_{11} & 0 \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} & 0 \\ R_{12} & 0 \end{pmatrix}, \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix}, \text{ if } p \geq n$$

or

$$\begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix}, \text{ if } p < n$$

where T_{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GRQ factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the RQ factorization of $\text{sub}(A) \cdot \text{inv}(\text{sub}(B))$:

$$\text{sub}(A) \cdot \text{inv}(\text{sub}(B)) = (R \cdot \text{inv}(T)) \cdot Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ ($m \geq 0$).
p	INTEGER. The number of rows in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
a	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf

	COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of size $(lld_a, LOCc(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix sub(A) to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of size $(lld_b, LOCc(jb+n-1))$. Contains the local pieces of the p -by- n matrix sub(B) to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.
<i>descb</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .
<i>work</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of <i>work</i> , must be at least $lwork \geq \max(mb_a * (mpa0 + nqa0 + mb_a), \max((mb_a * (mb_a - 1)) / 2, (ppb0 + nqb0) * mb_a) + mb_a * mb_a, nb_b * (ppb0 + nqb0 + nb_b))$, where $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW)$, $nqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$

```

iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW ),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL ),
ppb0 = numroc (p+iroffb, mb_b, MYROW, ibrow,NPROW),
nqb0 = numroc (n+icoffb, nb_b, MYCOL, ibcol,NPCOL)

```

NOTE

$\text{mod}(x,y)$ is the integer remainder of x/y .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

`a`

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array `taua`, represent the orthogonal/unitary matrix Q as a product of $\min(n,m)$ elementary reflectors (see *Application Notes* below).

`taua`, `taub`

(local)

REAL for `psggqrf`

DOUBLE PRECISION for `pdggqrf`

COMPLEX for `pcggqrf`

DOUBLE COMPLEX for `pzggqrf`.

Arrays of size $LOCr(ia+m-1)$ for `taua` and $LOCc(jb+\min(p,n)-1)$ for `taub`.

The array `taua` contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . `taua` is tied to the distributed matrix A . (See *Application Notes* below).

The array `taub` contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z . `taub` is tied to the distributed matrix B . (See *Application Notes* below).

`work(1)`

On exit `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.

= 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(i_a) * H(i_a+1) * \dots * H(i_a+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_a * v * v'$$

where τ_a is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(i_a+m-k+i-1, j_a:j_a+n-k+i-2)$, and τ_a in $\tau_a(i_a+m-k+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungrq](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmrq](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(j_b) * H(j_b+1) * \dots * H(j_b+k-1), \text{ where } k = \min(p, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_b * v * v'$$

where τ_b is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i_b+i:i_b+p-1, j_b+i-1)$, and τ_b in $\tau_b(j_b+i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

Symmetric Eigenproblems

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form T and then find the eigenvalues and eigenvectors of the tridiagonal matrix T . ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenproblems"](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the QTQ algorithm, or bisection followed by inverse iteration).

Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/ Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $A = QTQ^H$	p?sytrd/p?hetrd		
Multiply matrix after reduction		p?ormtr/p?unmtr	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a QTQ method			steqr2*
Find selected eigenvalues of a tridiagonal matrix T via bisection			p?stebz

Operation	Dense symmetric/ Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Find selected eigenvectors of a tridiagonal matrix T by inverse iteration			p?stein

* This routine is described as part of auxiliary ScaLAPACK routines.

[p?sytrd](#)

Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.

Syntax

```
call pssytrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Include Files

Description

The `p?sytrd` routine reduces a real symmetric matrix $\text{sub}(A)$ to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q^* \text{sub}(A) Q = T,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is stored: If <code>uplo</code> = 'U', upper triangular If <code>uplo</code> = 'L', lower triangular
<code>n</code>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pssytrd</code> DOUBLE PRECISION for <code>pdsytrd</code> . Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$. If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo</code> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See <i>Application Notes</i> below.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, size of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB),$ where $NB = mb_a = nb_a,$ $np = \text{numroc}(n, NB, MYROW, iarow, NPROW),$ $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW).$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors. See <i>Application Notes</i> below.
<i>d</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays of size <i>LOCc(ja+n-1)</i> . The diagonal elements of the tridiagonal matrix <i>T</i> : $d(i) = A(i,i).$ <i>d</i> is tied to the distributed matrix <i>A</i> .
<i>e</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd.

Arrays of size $LOCc(ja+n-1)$ if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e(i) = A(i, i+1)$ if $uplo = 'U'$,

$e(i) = A(i+1, i)$ if $uplo = 'L'$.

e is tied to the distributed matrix A .

tau

(local)

REAL for pssytrd

DOUBLE PRECISION for pdsytrd.

Arrays of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix A .

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of sub(A) on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

If `uplo = 'L'`:

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormtr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.

Syntax

```
call psormtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pdormtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

Description

This routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of nq elementary reflectors, as returned by [p?sytrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>uplo</i>	(global) CHARACTER. = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?sytrd
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(C) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(C) ($n \geq 0$).
<i>a</i>	(local) REAL for psormtr DOUBLE PRECISION for pdormtr. Pointer into the local memory to an array of size $(lld_a, LOCc(ja+m-1))$ if $side = 'L'$, and $(lld_a, LOCc(ja+n-1))$ if $side = 'R'$. Contains the vectors that define the elementary reflectors, as returned by p?sytrd. If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$; If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) REAL for psormtr DOUBLE PRECISION for pdormtr. Array of size of <i>ltau</i> where if $side = 'L'$ and $uplo = 'U'$, $ltau = LOCc(m_a)$,

if *side* = 'L' and *uplo* = 'L', *ltau* = LOCc(*ja*+*m*-2),

if *side* = 'R' and *uplo* = 'U', *ltau* = LOCc(*n*_a),

if *side* = 'R' and *uplo* = 'L', *ltau* = LOCc(*ja*+*n*-2).

tau(*i*) must contain the scalar factor of the elementary reflector *H*(*i*), as returned by p?sytrd. *tau* is tied to the distributed matrix *A*.

c

(local) REAL for psormtr

DOUBLE PRECISION for pdormtr.

Pointer into the local memory to an array of size (11*d*_c, LOCc(*jc*+*n*-1)). Contains the local pieces of the distributed matrix sub (*C*).

ic, jc

(global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc

(global and local) INTEGER array of size *d/en*_. The array descriptor for the distributed matrix *C*.

work

(local)

REAL for psormtr

DOUBLE PRECISION for pdormtr.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

if *uplo* = 'U',

iaa= *ia*; *jaa*= *ja*+1, *icc*= *ic*; *jcc*= *jc*;

else *uplo* = 'L',

iaa= *ia*+1, *jaa*= *ja*;

If *side* = 'L',

icc= *ic*+1; *jcc*= *jc*;

else *icc*= *ic*; *jcc*= *jc*+1;

end if

end if

If *side* = 'L',

mi= *m*-1; *ni*= *n*

lwork≥max((*nb*_a*(*nb*_a-1))/2, (*nqc*0 + *mpc*0)**nb*_a) + *nb*_a**nb*_a

else

If *side* = 'R',

mi= *m*; *mi* = *n*-1;

lwork≥max((*nb*_a*(*nb*_a-1))/2, (*nqc*0 +

max(*n*pa0+numroc(numroc(*ni*+*icoffc*, *nb*_a, 0, 0, NPCOL), *nb*_a, 0, 0, *lcmq*), *mpc*0))**nb*_a)+ *nb*_a**nb*_a

end if

```

where  $lcmq = lcm/NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,
 $iroffa = \text{mod}(iaa-1, mb\_a)$ ,
 $icoffa = \text{mod}(jaa-1, nb\_a)$ ,
 $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW)$ ,
 $npa0 = \text{numroc}(ni+iroffa, mb\_a, MYROW, iarow, NPROW)$ ,
 $iroffc = \text{mod}(icc-1, mb\_c)$ ,
 $icoffc = \text{mod}(jcc-1, nb\_c)$ ,
 $icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW)$ ,
 $iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL)$ ,
 $mpc0 = \text{numroc}(mi+iroffc, mb\_c, MYROW, icrow, NPROW)$ ,
 $nqc0 = \text{numroc}(ni+icoffc, nb\_c, MYCOL, iccol, NPCOL)$ ,

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$ilcm$, indxg2p and numroc are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the subroutine `blacs_gridinfo`. If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of $lwork$ required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

```

call pchetrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetrd(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)

```

Include Files

Description

The `p?hetrd` routine reduces a complex Hermitian matrix `sub(A)` to Hermitian tridiagonal form T by a unitary similarity transformation:

$$Q^* \text{sub}(A) Q = T$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the Hermitian matrix <code>sub(A)</code> is stored: If <code>uplo = 'U'</code> , upper triangular If <code>uplo = 'L'</code> , lower triangular
<code>n</code>	(global) INTEGER. The order of the distributed matrix <code>sub(A)</code> ($n \geq 0$).
<code>a</code>	(local) COMPLEX for <code>pchetrd</code> DOUBLE COMPLEX for <code>pzhetrdr</code> . Pointer into the local memory to an array of size $(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$. On entry, this array contains the local pieces of the Hermitian distributed matrix <code>sub(A)</code> . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see <i>Application Notes</i> below).
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<code>desca</code>	(global and local) INTEGER array of size <code>dlen_</code> . The array descriptor for the distributed matrix A .
<code>work</code>	(local) COMPLEX for <code>pchetrd</code> DOUBLE COMPLEX for <code>pzhetrdr</code> . Workspace array of size <code>lwork</code> .
<code>lwork</code>	(local or global) INTEGER, size of <code>work</code> , must be at least: $\text{lwork} \geq \max(\text{NB} * (\text{np} + 1), 3 * \text{NB})$ where $\text{NB} = \text{mb_a} = \text{nb_a}$, $\text{np} = \text{numroc}(n, \text{NB}, \text{MYROW}, \text{iarow}, \text{NPROW})$,

`iarow = indxg2p(ia, NB, MYROW, rsrc_a, NPROW).`

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	<p>On exit,</p> <p>If <code>uplo = 'U'</code>, the diagonal and first superdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal matrix <code>T</code>, and the elements above the first superdiagonal, with the array <code>tau</code>, represent the unitary matrix <code>Q</code> as a product of elementary reflectors; if <code>uplo = 'L'</code>, the diagonal and first subdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal matrix <code>T</code>, and the elements below the first subdiagonal, with the array <code>tau</code>, represent the unitary matrix <code>Q</code> as a product of elementary reflectors (see <i>Application Notes</i> below).</p>
<code>d</code>	<p>(local)</p> <p>REAL for <code>pchetrd</code></p> <p>DOUBLE PRECISION for <code>pzhetrdr</code>.</p> <p>Arrays of size <code>LOCc(ja+n-1)</code>. The diagonal elements of the tridiagonal matrix <code>T</code>:</p> <p>$d(i) = A(i,i)$.</p> <p><code>d</code> is tied to the distributed matrix <code>A</code>.</p>
<code>e</code>	<p>(local)</p> <p>REAL for <code>pchetrd</code></p> <p>DOUBLE PRECISION for <code>pzhetrdr</code>.</p> <p>Arrays of size <code>LOCc(ja+n-1)</code> if <code>uplo = 'U'</code>; <code>LOCc(ja+n-2)</code> - otherwise.</p> <p>The off-diagonal elements of the tridiagonal matrix <code>T</code>:</p> <p>$e(i) = A(i,i+1)$ if <code>uplo = 'U'</code>,</p> <p>$e(i) = A(i+1,i)$ if <code>uplo = 'L'</code>.</p> <p><code>e</code> is tied to the distributed matrix <code>A</code>.</p>
<code>tau</code>	<p>(local) COMPLEX for <code>pchetrd</code></p> <p>DOUBLE COMPLEX for <code>pzhetrdr</code>.</p> <p>Array of size <code>LOCc(ja+n-1)</code>. This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix <code>A</code>.</p>
<code>work(1)</code>	<p>On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.</p>
<code>info</code>	<p>(global) INTEGER.</p>

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1)*...*H(2)*H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*...*H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of $sub(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?unmtr

Multiplies a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.

Syntax

```
call pcunmtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

```
call pzunmtr(side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files**Description**

This routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by [p?hetrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied.
$uplo$	(global) CHARACTER. $= 'U'$: Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd ; $= 'L'$: Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(<i>C</i>) ($n \geq 0$).
<i>a</i>	<p>(local)</p> <p>REAL for pcunmtr</p> <p>DOUBLE PRECISION for pzunmtr.</p> <p>Pointer into the local memory to an array of size $(lld_a, LOCc(ja+m-1))$ if <i>side</i> = 'L', and $(lld_a, LOCc(ja+n-1))$ if <i>side</i> = 'R'.</p> <p>Contains the vectors which define the elementary reflectors, as returned by p?hetrd.</p> <p>If <i>side</i>='L', $lld_a \geq \max(1, LOCr(ia+m-1))$;</p> <p>If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	<p>(local)</p> <p>COMPLEX for pcunmtr</p> <p>DOUBLE COMPLEX for pzunmtr.</p> <p>Array of size of <i>ltau</i> where</p> <p>If <i>side</i> = 'L' and <i>uplo</i> = 'U', <i>ltau</i> = $LOCc(m_a)$,</p> <p>if <i>side</i> = 'L' and <i>uplo</i> = 'L', <i>ltau</i> = $LOCc(ja+m-2)$,</p> <p>if <i>side</i> = 'R' and <i>uplo</i> = 'U', <i>ltau</i> = $LOCc(n_a)$,</p> <p>if <i>side</i> = 'R' and <i>uplo</i> = 'L', <i>ltau</i> = $LOCc(ja+n-2)$.</p> <p><i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector <i>H</i>(<i>i</i>), as returned by p?hetrd. <i>tau</i> is tied to the distributed matrix <i>A</i>.</p>
<i>c</i>	<p>(local) COMPLEX for pcunmtr</p> <p>DOUBLE COMPLEX for pzunmtr.</p> <p>Pointer into the local memory to an array of size $(lld_c, LOCc(jc+n-1))$.</p> <p>Contains the local pieces of the distributed matrix sub (<i>C</i>).</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	<p>(local)</p> <p>COMPLEX for pcunmtr</p> <p>DOUBLE COMPLEX for pzunmtr.</p>

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

```

If uplo = 'U',
  iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
  iaa= ia+1, jaa= ja;
If side = 'L',
  icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
  mi= m-1; ni= n
  lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
else
  If side = 'R',
    mi= m; ni = n-1;
    lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a,
0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
end if
where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
  iroffa = mod(iaa-1, mb_a),
  icoffa = mod(jaa-1, nb_a),
  iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
  npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
  iroffc = mod(icc-1, mb_c),
  icoffc = mod(jcc-1, nb_c),
  icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
  iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
  mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
  nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

```
call psstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, liwork, info)
```

```
call pdstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, liwork, info)
```

Include Files

Description

The `p?stebz` routine computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval `[vl,vu]`, or the eigenvalues indexed `il` through `iu`. A static partitioning of work is done at the beginning of `p?stebz` which results in all processes finding an (almost) equal number of eigenvalues.

Notice revision #20110804

Input Parameters

<i>ictxt</i>	(global) INTEGER. The BLACS context handle.
<i>range</i>	<p>(global) CHARACTER. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues in the interval [<i>vl</i>, <i>vu</i>].</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.</p>
<i>order</i>	<p>(global) CHARACTER. Must be 'B' or 'E'.</p> <p>If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block.</p> <p>If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.</p>
<i>n</i>	(global) INTEGER. The order of the tridiagonal matrix T ($n \geq 0$).
<i>vl, vu</i>	<p>(global)</p> <p>REAL for <i>psstebz</i></p> <p>DOUBLE PRECISION for <i>pdstebz</i>.</p> <p>If <i>range</i> = 'V', the routine computes the lower and the upper bounds for the eigenvalues on the interval [<i>l</i>, <i>vu</i>].</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>(global)</p> <p>INTEGER. Constraint: $1 \leq il \leq iu \leq n$.</p> <p>If <i>range</i> = 'I', the index of the smallest eigenvalue is returned for <i>il</i> and of the largest eigenvalue for <i>iu</i> (assuming that the eigenvalues are in ascending order) must be returned.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>(global)</p> <p>REAL for <i>psstebz</i></p> <p>DOUBLE PRECISION for <i>pdstebz</i>.</p> <p>The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width <i>abstol</i>. If <i>abstol</i> ≤ 0, then the tolerance is taken as $ulp T$, where <i>ulp</i> is the machine precision, and T means the 1-norm of T</p>

Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), *abstol* should be set to `2*p?lamch('S')`.

<i>d</i>	<p>(global)</p> <p>REAL for <code>psstebz</code></p> <p>DOUBLE PRECISION for <code>pdstebz</code>.</p> <p>Array of size <i>n</i>.</p> <p>Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.</p>
<i>e</i>	<p>(global)</p> <p>REAL for <code>psstebz</code></p> <p>DOUBLE PRECISION for <code>pdstebz</code>.</p> <p>Array of size <i>n</i> - 1.</p> <p>Contains (<i>n</i>-1) off-diagonal elements of the tridiagonal matrix <i>T</i>. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.</p>
<i>work</i>	<p>(local)</p> <p>REAL for <code>psstebz</code></p> <p>DOUBLE PRECISION for <code>pdstebz</code>.</p> <p>Array of size <code>max(5<i>n</i>, 7)</code>. This is a workspace array.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the <i>work</i> array must be <math>\geq \text{max}(5<i>n</i>, 7)</math>.</p> <p>If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code>.</p>
<i>iwork</i>	<p>(local) INTEGER. Array of size <code>max(4<i>n</i>, 14)</code>. This is a workspace array.</p>
<i>liwork</i>	<p>(local) INTEGER. The size of the <i>iwork</i> array must <math>\geq \text{max}(4<i>n</i>, 14, \text{NPROCS})</math>.</p> <p>If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code>.</p>

Output Parameters

<i>m</i>	(global) INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$
----------	---

<i>nsplit</i>	(global) INTEGER. The number of diagonal blocks detected in T . $1 \leq nsplit \leq n$
<i>w</i>	(global) REAL for <code>psstebz</code> DOUBLE PRECISION for <code>pdstebz</code> . Array of size n . On exit, the first m elements of w contain the eigenvalues on all processes.
<i>iblock</i>	(global) INTEGER. Array of size n . At each row/column j where $e(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit <i>iblock</i> (i) specifies which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs to.

NOTE

In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

<i>isplit</i>	(global) INTEGER. Array of size n . Contains the splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), and so on, and the <i>nsplit</i> -th submatrix consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= n . (Only the first <i>nsplit</i> elements are used, but since the <i>nsplit</i> values are not known, n words must be reserved for <i>isplit</i> .)
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if <i>info</i> = - i , the i -th argument has an illegal value. If <i>info</i> > 0, some or all of the eigenvalues fail to converge or are not computed. If <i>info</i> = 1, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. If <i>info</i> = 2, mismatch between the number of eigenvalues output and the number desired. If <i>info</i> = 3: <i>range</i> ='I', and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the <i>fudge</i> parameter, recompile, and try again.

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

```
call psstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pdstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pcstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)

call pzstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work, lwork,
iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

Description

The `p?stein` routine computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK routine) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

$p = \text{NPROW} * \text{NPCOL}$ is the total number of processes.

Input Parameters

<code>n</code>	(global) INTEGER. The order of the matrix T ($n \geq 0$).
<code>m</code>	(global) INTEGER. The number of eigenvectors to be returned.
<code>d, e, w</code>	(global) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <code>d</code> of size n contains the diagonal elements of T . <code>e</code> of size $n-1$ contains the off-diagonal elements of T . <code>w</code> of size m contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array <code>w</code> from <code>p?stebz</code> with order = 'B' is expected. The array should be replicated in all processes.)
<code>iblock</code>	(global) INTEGER.

Array of size n . The submatrix indices associated with the corresponding eigenvalues in w : 1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array $iblock$ from `p?stebz` is expected here).

isplit

(global) INTEGER.

Array of size n . The splitting points at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, and so on, and the $nsplit$ -th submatrix consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$. (The output array $isplit$ from `p?stebz` is expected here.)

orfac

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

orfac specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within $orfac*||T||$ of each other are to be orthogonalized. However, if the workspace is insufficient (see *lwork*), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if *orfac* is equal to zero. A default value of 1000 is used if *orfac* is negative. *orfac* should be identical on all processes

iz, jz

(global) INTEGER. The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix Z .

work

(local). REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array of size *lwork*.

lwork

(local) INTEGER.

lwork controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00))/n)$. Eigenvectors corresponding to eigenvalue clusters of size $(nvec - \text{ceil}(m/p) + 1)$ are guaranteed to be orthogonal (the orthogonality is similar to that obtained from `?stein2`).

NOTE

lwork must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p)*n$ and should have the same input value on all processes.

It is the minimum value of *lwork* input on different processes that is significant.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

$iwork$ (local) INTEGER.

Workspace array of size $3n+p+1$.

$liwork$ (local) INTEGER. The size of the array $iwork$. It must be greater than $3*n+p+1$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

z (local)

REAL for `psstein`

DOUBLE PRECISION for `pdstein`

COMPLEX for `pcstein`

DOUBLE COMPLEX for `pzstein`.

Array of size $descz(dlen_), n/NPCOL + NB$. z contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [?stein2](#)). On output, z is distributed across the p processes in block cyclic format.

$work(1)[0]$ On exit, $work(1)$ gives a lower bound on the workspace ($lwork$) that guarantees the user desired orthogonalization (see `orfac`). Note that this may overestimate the minimum workspace needed.

$iwork$ On exit, $iwork(1)$ contains the amount of integer workspace required.

On exit, the $iwork(2)$ through $iwork(p+2)$ indicate the eigenvectors computed by each process. Process i computes eigenvectors indexed $iwork(i+2)+1$ through $iwork(i+3)$.

$ifail$ (global) INTEGER. Array of size m . On normal exit, all elements of $ifail$ are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in [?stein](#)), then $info > 0$ is returned. If $\text{mod}(info, m+1) > 0$, then for $i=1$ to $\text{mod}(info, m+1)$, the eigenvector corresponding to the eigenvalue $w(ifail(i))$ failed to converge (w refers to the array of eigenvalues on output).

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$iclustr$ (global) INTEGER. Array of size $2*p$.

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr(2*I-1)$ to $iclustr(2*I)$, $i = 1$ to $info/(m+1)$, could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array: $iclustr(2*k) \neq 0$ and $iclustr(2*k+1) = 0$ if and only if k is the number of clusters.

gap

(global)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The $info/m$ output values in this array correspond to the $info/(m+1)$ clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(O(n) * macheps) / gap(i)$.

info

(global) INTEGER.

If $info = 0$, the execution is successful.

If $info < 0$: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then $info = -(i*100+j)$,

If the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

If $info < 0$: if $info = -i$, the *i*-th argument had an illegal value.

If $info > 0$: if $\text{mod}(info, m+1) = i$, then *i* eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If $info/(m+1) = i$, then eigenvectors corresponding to *i* clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table "Computational Routines for Solving Nonsymmetric Eigenproblems" lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	p?gehrd		
Multiply the matrix after reduction		p?ormhr / p?unmhr	

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Find eigenvalues and Schur factorization			p?lahqr , p?hseqr

p?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

```
call psgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehrd(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

Description

The `p?gehrd` routine reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal or unitary similarity transformation

$$Q^* \text{sub}(A) Q = H,$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{ilo}-2$ and $\text{ja}+\text{ihi}:\text{ja}+n-1$. (See <i>Application Notes</i> below). If $n > 0$, $1 \leq \text{ilo} \leq \text{ihi} \leq n$; otherwise set $\text{ilo} = 1$, $\text{ihi} = n$.
<i>a</i>	(local) REAL for <code>psgehrd</code> DOUBLE PRECISION for <code>pdgehrd</code> COMPLEX for <code>pcgehrd</code> DOUBLE COMPLEX for <code>pzgehrd</code> . Pointer into the local memory to an array of size $(\text{lld_a}, \text{LOCc}(\text{ja}+n-1))$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local)

REAL for psgehrd
 DOUBLE PRECISION for pdgehrd
 COMPLEX for pcgehrd
 DOUBLE COMPLEX for pzgehrd.
 Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of the array *work*. *lwork* is local input and must be at least

$lwork \geq NB * NB + NB * \max(ihip+1, ihlp+inlq)$

where $NB = mb_a = nb_a$,

$iroffa = \text{mod}(ia-1, NB)$,

$icoffa = \text{mod}(ja-1, NB)$,

$ioff = \text{mod}(ia+ilo-2, NB)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$, $ihip = \text{numroc}(ihi+iroffa, NB, MYROW, iarow, NPROW)$,

$ilrow = \text{indxg2p}(ia+ilo-1, NB, MYROW, rsrc_a, NPROW)$,

$ihlp = \text{numroc}(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPROW)$,

$ilcol = \text{indxg2p}(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL)$,

$inlq = \text{numroc}(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, the upper triangle and the first subdiagonal of *sub(A)* are overwritten with the upper Hessenberg matrix *H*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau

(local). REAL for psgehrd

DOUBLE PRECISION for pdgehrd

COMPLEX for pcgehrd

DOUBLE COMPLEX for pzgehrd.

Array of size at least $\max(ja+n-2)$.

The scalar factors of the elementary reflectors (see *Application Notes* below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of the global vector τ are set to zero. τ is tied to the distributed matrix A .

$work(1)$

On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*...*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $a(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and τ in $\tau(ja+ilo+i-2)$. The contents of

$a(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ v2 & h & h & h & h & h & \\ v2 & v3 & h & h & h & h & \\ v2 & v3 & v4 & h & h & h & \\ & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?ormhr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```
call psormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Include Files

Description

The `p?ormhr` routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

$side$ (global) CHARACTER
 $= 'L'$: Q or Q^T is applied from the left.

= 'R': Q or Q^T is applied from the right.

trans

(global) CHARACTER

= 'N', no transpose, Q is applied.

= 'T', transpose, Q^T is applied.

m

(global) INTEGER. The number of rows in the distributed matrix sub (C) ($m \geq 0$).

n

(global) INTEGER. The number of columns in the distributed matrix sub (C) ($n \geq 0$).

ilo, ihi

(global) INTEGER.

ilo and *ihi* must have the same values as in the previous call of `p?gehrd`. Q is equal to the unit matrix except for the distributed submatrix $Q(ia + ilo:ia + ihi - 1, ja + ilo:ja + ihi - 1)$.

If *side* = 'L', $1 \leq ilo \leq ihi \leq \max(1, m)$;

If *side* = 'R', $1 \leq ilo \leq ihi \leq \max(1, n)$;

ilo and *ihi* are relative indexes.

a

(local)

REAL for `psormhr`

DOUBLE PRECISION for `pdormhr`

Pointer into the local memory to an array of size $(lld_a, LOCc(ja + m - 1))$ if *side* = 'L', and $(lld_a, LOCc(ja + n - 1))$ if *side* = 'R'.

Contains the vectors which define the elementary reflectors, as returned by `p?gehrd`.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix A .

tau

(local)

REAL for `psormhr`

DOUBLE PRECISION for `pdormhr`

Array of size $LOCc(ja + m - 2)$ if *side* = 'L', and $LOCc(ja + n - 2)$ if *side* = 'R'.

tau(j) contains the scalar factor of the elementary reflector $H(j)$ as returned by `p?gehrd`. *tau* is tied to the distributed matrix A .

c

(local)

REAL for `psormhr`

DOUBLE PRECISION for `pdormhr`

Pointer into the local memory to an array of size $(lld_c, LOCC(jc+n-1))$.
Contains the local pieces of the distributed matrix sub(C).

ic, jc

(global) INTEGER. The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C, respectively.

descc

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix C.

work

(local)

REAL for psormhr

DOUBLE PRECISION for pdormhr

Workspace array with size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*.

lwork must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$

If *side* = 'L',

$mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$

else if *side* = 'R',

$mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + iroffa, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$

end if

where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,

$iroffa = \text{mod}(iaa - 1, mb_a),$

$icoffa = \text{mod}(jaa - 1, nb_a),$

$iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW),$

$npa0 = \text{numroc}(ni + iroffa, mb_a, MYROW, iarow, NPROW),$

$iroffc = \text{mod}(icc - 1, mb_c), icoffc = \text{mod}(jcc - 1, nb_c),$

$icrow = \text{indxg2p}(icc, mb_c, MYROW, rsrc_c, NPROW),$

$iccol = \text{indxg2p}(jcc, nb_c, MYCOL, csrc_c, NPCOL),$

$mpc0 = \text{numroc}(mi + iroffc, mb_c, MYROW, icrow, NPROW),$

$nqc0 = \text{numroc}(ni + icoffc, nb_c, MYCOL, iccol, NPCOL),$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	<code>sub(C)</code> is overwritten by $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Description

This routine overwrites the general complex distributed *m*-by-*n* matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q*\text{sub}(C)$	$\text{sub}(C)*Q$
<i>trans</i> = 'H':	$Q^H*\text{sub}(C)$	$\text{sub}(C)*Q^H$

where *Q* is a complex unitary distributed matrix of order *nq*, with $nq = m$ if *side* = 'L' and $nq = n$ if *side* = 'R'.

Q is defined as the product of *ihi-ilo* elementary reflectors, as returned by [p?gehrd](#).

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

<i>side</i>	<p>(global) CHARACTER</p> <p>= 'L': Q or Q^H is applied from the left.</p> <p>= 'R': Q or Q^H is applied from the right.</p>
<i>trans</i>	<p>(global) CHARACTER</p> <p>= 'N', no transpose, Q is applied.</p> <p>= 'C', conjugate transpose, Q^H is applied.</p>

<i>work</i>	<p>(local)</p> <p>COMPLEX for pcunmhr</p> <p>DOUBLE COMPLEX for pzunmhr.</p> <p>Workspace array with size <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global)</p> <p>The size of the array <i>work</i>.</p> <p><i>lwork</i> must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$</p> <p>If <i>side</i> = 'L', $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$</p> <p>else if <i>side</i> = 'R',</p> <p>$mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 +$ $\max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb_a, 0, 0, NPCOL), nb_a,$ $0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$</p> <p>end if</p> <p>where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL),$</p> <p>$iroffa = \text{mod}(iaa - 1, mb_a),$</p> <p>$icoffa = \text{mod}(jaa - 1, nb_a),$</p> <p>$iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW),$</p> <p>$npa0 = \text{numroc}(ni + iroffa, mb_a, MYROW, iarow, NPROW),$</p> <p>$iroffc = \text{mod}(icc - 1, mb_c),$</p> <p>$icoffc = \text{mod}(jcc - 1, nb_c),$</p> <p>$icrow = \text{indxg2p}(icc, mb_c, MYROW, rsrc_c, NPROW),$</p> <p>$iccol = \text{indxg2p}(jcc, nb_c, MYCOL, csrc_c, NPCOL),$</p> <p>$mpc0 = \text{numroc}(mi + iroffc, mb_c, MYROW, icrow, NPROW),$</p> <p>$nqc0 = \text{numroc}(ni + icoffc, nb_c, MYCOL, iccol, NPCOL),$</p>

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pserbla`.

Output Parameters

<code>c</code>	<code>C</code> is overwritten by $Q^* \text{sub}(C)$ or $Q'^* \text{sub}(C)$ or $\text{sub}(C) * Q'$ or $\text{sub}(C) * Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

```
call pslahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info)
```

```
call pdlahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z, descz, work,
lwork, iwork, ilwork, info)
```

Include Files**Description**

This is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns `ilo` and `ihi`.

Input Parameters

<code>wantt</code>	(global) LOGICAL If <code>wantt</code> = .TRUE., the full Schur form T is required; If <code>wantt</code> = .FALSE., only eigenvalues are required.
--------------------	---

<i>wantz</i>	<p>(global) LOGICAL.</p> <p>If <i>wantz</i> = .TRUE., the matrix of Schur vectors <i>Z</i> is required;</p> <p>If <i>wantz</i> = .FALSE., Schur vectors are not required.</p>
<i>n</i>	<p>(global) INTEGER. The order of the Hessenberg matrix <i>A</i> (and <i>z</i> if <i>wantz</i>). $n \geq 0$.</p>
<i>ilo, ihi</i>	<p>(global) INTEGER.</p> <p>It is assumed that <i>A</i> is already upper quasi-triangular in rows and columns <i>ihi</i>+1:<i>n</i>, and that $A(i_{lo}, i_{lo}-1) = 0$ (unless <i>ilo</i> = 1). <i>p?lahqr</i> works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i>, but applies transformations to all of <i>H</i> if <i>wantt</i> is .TRUE..</p> <p>$1 \leq i_{lo} \leq \max(1, i_{hi}); i_{hi} \leq n$.</p>
<i>a</i>	<p>(global)</p> <p>REAL for <i>pslahqr</i></p> <p>DOUBLE PRECISION for <i>pdlahqr</i></p> <p>Array, of size (<i>lld_a</i>, *). On entry, the upper Hessenberg matrix <i>A</i>.</p>
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p>
<i>iloz, ihiz</i>	<p>(global) INTEGER. Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq i_{loz} \leq i_{lo}; i_{hi} \leq i_{hiz} \leq n$.</p>
<i>z</i>	<p>(global)REAL for <i>pslahqr</i></p> <p>DOUBLE PRECISION for <i>pdlahqr</i></p> <p>Array. If <i>wantz</i> is .TRUE., on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations accumulated by <i>pdhseqr</i>. If <i>wantz</i> is .FALSE., <i>z</i> is not referenced.</p>
<i>descz</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>Z</i>.</p>
<i>work</i>	<p>(local)</p> <p>REAL for <i>pslahqr</i></p> <p>DOUBLE PRECISION for <i>pdlahqr</i></p> <p>Workspace array with size <i>lwork</i>.</p>
<i>lwork</i>	<p>(local) INTEGER. The size of <i>work</i>. <i>lwork</i> is assumed big enough so that $lwork \geq 3*n + \max(2*\max(lld_z, lld_a) + 2*LOCq(n), 7*ceil(n/hbl)/lcm(NPROW, NPCOL))$.</p> <p>If <i>lwork</i> = -1, then <i>work</i>(1) gets set to the above number and the code returns immediately.</p>
<i>iwork</i>	<p>(global and local) INTEGER array of size <i>ilwork</i>.</p>
<i>ilwork</i>	<p>(local) INTEGER This holds some of the <i>iblk</i> integer arrays.</p>

Output Parameters

<i>a</i>	On exit, if <i>wantt</i> is <code>.TRUE.</code> , <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> is <code>.FALSE.</code> , the contents of <i>A</i> are unspecified on exit.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>wr, wi</i>	(global replicated output) REAL for pslahqr DOUBLE PRECISION for pdlahqr Arrays of size <i>n</i> each. The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> + 1)-th, with <i>wi</i> (<i>i</i>) > 0 and <i>wi</i> (<i>i</i> + 1) < 0. If <i>wantt</i> is <code>.TRUE.</code> , the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>A</i> . <i>A</i> may be returned with larger diagonal blocks until the next release.
<i>z</i>	On exit <i>z</i> has been updated; transformations are applied only to the submatrix <i>Z</i> (<i>iloz:ihiz</i> , <i>ilo:ihi</i>).
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: the parameter number - <i>info</i> is incorrect or inconsistent > 0: p?lahqr failed to compute all the eigenvalues <i>ilo</i> to <i>ihi</i> in a total of 30*(<i>ihi</i> - <i>ilo</i> +1) iterations; if <i>info</i> = <i>i</i> , elements <i>i</i> +1: <i>ihi</i> of <i>wr</i> and <i>wi</i> contain the eigenvalues that have been successfully computed.

p?hseqr

Computes eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

```
call pshseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
```

```
call pdhseqr( job, compz, n, ilo, ihi, h, desch, wr, wi, z, descz, work, lwork, iwork, liwork, info )
```

Include Files

Description

p?hseqr computes the eigenvalues of an upper Hessenberg matrix *H* and, optionally, the matrices *T* and *Z* from the Schur decomposition $H = Z^*T^*Z^T$, where *T* is an upper quasi-triangular matrix (the Schur form), and *Z* is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q*H*Q^T = (QZ)*T*(QZ)^T$.

Input Parameters

<i>job</i>	<p>(global) CHARACTER*1</p> <p>= 'E': compute eigenvalues only;</p> <p>= 'S': compute eigenvalues and the Schur form T.</p>
<i>compz</i>	<p>(global) CHARACTER*1</p> <p>= 'N': no Schur vectors are computed;</p> <p>= 'I': z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned;</p> <p>= 'V': z must contain an orthogonal matrix Q on entry, and the product $Q*Z$ is returned.</p>
<i>n</i>	<p>(global) INTEGER</p> <p>The order of the Hessenberg matrix H. $n \geq 0$.</p>
<i>ilo, ihi</i>	<p>(global) INTEGER</p> <p>It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. <i>ilo</i> and <i>ihi</i> are normally set by a previous call to p?gebal, and then passed to p?gehrd when the matrix output by p?gebal is reduced to Hessenberg form. Otherwise <i>ilo</i> and <i>ihi</i> should be set to 1 and n respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$.</p> <p>If $n = 0$, then $ilo = 1$ and $ihi = 0$.</p>
<i>h</i>	<p>REAL for pshseqr</p> <p>DOUBLE PRECISION for pdhseqr</p> <p>(global) array of size (<i>desch</i>(<i>lld_</i>),<i>LOC</i>_c(n))</p> <p>The upper Hessenberg matrix H.</p>
<i>desch</i>	<p>(global and local) INTEGER array of size <i>dlen_</i></p> <p>The array descriptor for the distributed matrix H.</p>
<i>z</i>	<p>REAL for pshseqr</p> <p>DOUBLE PRECISION for pdhseqr</p> <p>(global) array</p> <p>If <i>compz</i> = 'V', on entry z must contain the current matrix Z of accumulated transformations from, for example, p?gehrd.</p> <p>If <i>compz</i> = 'I', on entry z need not be set.</p>
<i>descz</i>	<p>(global and local) INTEGER array of size <i>dlen_</i></p> <p>The array descriptor for the distributed matrix z.</p>
<i>work</i>	<p>REAL for pshseqr</p>

DOUBLE PRECISION for pdhseqr
(local workspace) array of size *lwork*.

lwork (local) INTEGER
The length of the workspace array *work*.

iwork (local workspace) INTEGER array of size *liwork*

liwork (local) INTEGER
The length of the workspace array *iwork*.

OUTPUT Parameters

h If *job* = 'S', *H* is upper quasi-triangular in rows and columns *ilo:ihi*, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $h(i,i) = h(i+1,i+1)$ and $h(i+1,i)*h(i,i+1) < 0$. If *info* = 0 and *job* = 'E', the contents of *h* are unspecified on exit.

wr, wi REAL for pshseqr
DOUBLE PRECISION for pdhseqr
(global) array of size *n*
The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)th, with $wi(i) > 0$ and $wi(i+1) < 0$. If *job* = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*.

z REAL for pshseqr
DOUBLE PRECISION for pdhseqr
(global) array
z is updated; transformations are applied only to the submatrix $z(ilo:ihi, ilo:ihi)$.
If *compz* = 'N', *z* is not referenced.
If *compz* = 'I' and *info* = 0, *z* contains the orthogonal matrix *Z* of the Schur vectors of *H*.

info INTEGER
= 0: successful exit
< 0: if *info* = -*i*, the *i*-th argument had an illegal value (see also below for -7777 and -8888).
> 0: if *info* = *i*, p?hseqr failed to compute all of the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed. (Failures are rare.)

If *info* > 0 and *job* = 'E', then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final, output value of *H*.

If *info* > 0 and *job* = 'S', then on exit (*) (initial value of *H*)**U* = *U**(final value of *H*) where *U* is an orthogonal matrix. The final value of *H* is upper Hessenberg and quasi-triangular in rows and columns *info*+1 through *ihi*.

If *info* > 0 and *compz* = 'V', then on exit (final value of *Z*) = (initial value of *Z*)**U* where *U* is the orthogonal matrix in (*) (regardless of the value of *job*.)

If *info* > 0 and *compz* = 'I', then on exit (final value of *Z*) = *U* where *U* is the orthogonal matrix in (*) (regardless of the value of *job*.)

If *info* > 0 and *compz* = 'N', then *z* is not accessed.

= -7777: `p?laqr0` failed to converge and `p?laqr1` was called instead.

= -8888: `p?laqr1` failed to converge and `p?laqr0` was called instead.

Singular Value Decomposition

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general *m*-by-*n* matrix *A* (see "[Singular Value Decomposition](#)" in LAPACK chapter).

To find the SVD of a general matrix *A*, this matrix is first reduced to a bidiagonal matrix *B* by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of *B* is computed using the LAPACK routine `?bdsqr`.

Table "[Computational Routines for Singular Value Decomposition \(SVD\)](#)" lists ScaLAPACK computational routines for performing this decomposition.

Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce <i>A</i> to a bidiagonal matrix	<code>p?gebrd</code>	
Multiply matrix after reduction		<code>p?ormbr/p?unmbr</code>

`p?gebrd`

Reduces a general matrix to bidiagonal form.

Syntax

```
call psgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Include Files

Description

The `p?gebrd` routine reduces a real/complex general *m*-by-*n* distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ to upper or lower bidiagonal form *B* by an orthogonal/unitary transformation:

$$Q^* \text{sub}(A) P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrix sub(A) ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix sub(A) ($n \geq 0$).
a	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Real pointer into the local memory to an array of size $(lld_a, LOCC(ja + n - 1))$. On entry, this array contains the distributed matrix sub (A).
ia, ja	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
$work$	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Workspace array of size $lwork$.
$lwork$	(local or global) INTEGER, size of $work$, must be at least: $lwork \geq nb * (mpa0 + nqa0 + 1) + nqa0$ where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia - 1, nb)$, $icoffa = \text{mod}(ja - 1, nb)$, $iarow = \text{indxg2p}(ia, nb, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb, MYCOL, csrc_a, NPCOL)$, $mpa0 = \text{numroc}(m + iroffa, nb, MYROW, iarow, NPROW)$, $nqa0 = \text{numroc}(n + icoffa, nb, MYCOL, iacol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i> , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array <i>taup</i> , represent the orthogonal matrix P as a product of elementary reflectors. See <i>Application Notes</i> below.
<i>d</i>	(local) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$ and $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d(i) = a(i, i)$. <i>d</i> is tied to the distributed matrix A .
<i>e</i>	(local) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array of size $LOCr(ia+\min(m,n)-1)$ if $m \geq n$; $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B : If $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$. <i>e</i> is tied to the distributed matrix A .
<i>tauq, taup</i>	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd.

Arrays of size $LOCc(ja+\min(m,n)-1)$ for τ_{auq} and $LOCr(ia+\min(m,n)-1)$ for τ_{aup} . Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices Q and P , respectively. τ_{auq} and τ_{aup} are tied to the distributed matrix A . See *Application Notes* below.

$work(1)$

On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.

$info$

(global) INTEGER.

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*\dots*H(n), \text{ and } P = G(1)*G(2)*\dots*G(n-1).$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{auq} * v * v' \text{ and } G(i) = I - \tau_{aup} * u * u'$$

where τ_{auq} and τ_{aup} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{auq} is stored in $\tau_{auq}(ja+i-1)$ and τ_{aup} in $\tau_{aup}(ia+i-1)$.

If $m < n$,

$$Q = H(1)*H(2)*\dots*H(m-1), \text{ and } P = G(1)*G(2)*\dots*G(m)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{auq} * v * v' \text{ and } G(i) = I - \tau_{aup} * u * u'$$

here τ_{auq} and τ_{aup} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{auq} is stored in $\tau_{auq}(ja+i-1)$ and τ_{aup} in $\tau_{aup}(ia+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6 (m < n)$:

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call psormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Include Files

Description

If $vect = 'Q'$, the `p?ormbr` routine overwrites the general real distributed m -by- n matrix $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q \ sub(C)$	$sub(C) \ Q$
$trans = 'T':$	$Q^T \ sub(C)$	$sub(C) \ Q^T$

If $vect = 'P'$, the routine overwrites $sub(C)$ with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$P \text{ sub}(C)$	$\text{sub}(C) P$
<i>trans</i> = 'T':	$P^T \text{ sub}(C)$	$\text{sub}(C) P^T$

Here Q and P^T are the orthogonal distributed matrices determined by `p?gebrd` when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if *side* = 'L' and $nq = n$ if *side* = 'R'. Therefore nq is the order of the orthogonal matrix Q or P^T that is applied.

If *vect* = 'Q', $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If *vect* = 'P', $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If <i>vect</i> = 'Q', then Q or Q^T is applied. If <i>vect</i> = 'P', then P or P^T is applied.
<i>side</i>	(global) CHARACTER. If <i>side</i> = 'L', then Q or Q^T , P or P^T is applied from the left. If <i>side</i> = 'R', then Q or Q^T , P or P^T is applied from the right.
<i>trans</i>	(global) CHARACTER. If <i>trans</i> = 'N', no transpose, Q or P is applied. If <i>trans</i> = 'T', then Q^T or P^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (C).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (C).
<i>k</i>	(global) INTEGER. If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$.
<i>a</i>	(local) REAL for <code>psormbr</code> DOUBLE PRECISION for <code>pdormbr</code> .

	<p>Pointer into the local memory to an array of size $(lld_a, LOCc(ja + \min(nq, k) - 1))$ if $vect = 'Q'$, and $(lld_a, LOCc(ja + nq - 1))$ if $vect = 'P'$.</p> <p>$nq = m$ if $side = 'L'$, and $nq = n$ otherwise.</p> <p>The vectors that define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by <code>p?gebrd</code>.</p> <p>If $vect = 'Q'$, $lld_a \geq \max(1, LOCr(ia + nq - 1))$;</p> <p>If $vect = 'P'$, $lld_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>tau</i>	<p>(local)</p> <p>REAL for <code>psormbr</code></p> <p>DOUBLE PRECISION for <code>pdormbr</code>.</p> <p>Array of size $LOCc(ja + \min(nq, k) - 1)$, if $vect = 'Q'$, and $LOCr(ia + \min(nq, k) - 1)$, if $vect = 'P'$.</p> <p>$tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$</p> <p>which determines Q or P, as returned by <code>pdgebrd</code> in its array argument $tauq$ or $taup$. tau is tied to the distributed matrix A.</p>
<i>c</i>	<p>(local) REAL for <code>psormbr</code></p> <p>DOUBLE PRECISION for <code>pdormbr</code></p> <p>Pointer into the local memory to an array of size $(lld_c, LOCc(jc + n - 1))$.</p> <p>Contains the local pieces of the distributed matrix sub (C).</p>
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>descc</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix C .
<i>work</i>	<p>(local)</p> <p>REAL for <code>psormbr</code></p> <p>DOUBLE PRECISION for <code>pdormbr</code>.</p> <p>Workspace array of size $lwork$.</p>
<i>lwork</i>	<p>(local or global) INTEGER, size of $work$, must be at least:</p> <p>If $side = 'L'$</p> <p>$nq = m$;</p>

```

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call pcunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Include Files

Description

If $vect = 'Q'$, the `p?unmbr` routine overwrites the general complex distributed m -by- n matrix $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

If $vect = 'P'$, the routine overwrites $sub(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P * sub(C)$	$sub(C) * P$
$trans = 'C':$	$P^H * sub(C)$	$sub(C) * P^H$

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q * B * P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Therefore nq is the order of the unitary matrix Q or P^H that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

$vect$	(global) CHARACTER. If $vect = 'Q'$, then Q or Q^H is applied. If $vect = 'P'$, then P or P^H is applied.
$side$	(global) CHARACTER. If $side = 'L'$, then Q or Q^H , P or P^H is applied from the left. If $side = 'R'$, then Q or Q^H , P or P^H is applied from the right.
$trans$	(global) CHARACTER. If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'C'$, conjugate transpose, Q^H or P^H is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $sub(C)$ $m \geq 0$.
n	(global) INTEGER. The number of columns in the distributed matrix $sub(C)$ $n \geq 0$.
k	(global) INTEGER.

If *vect* = 'Q', the number of columns in the original distributed matrix reduced by *p?gebrd*;

If *vect* = 'P', the number of rows in the original distributed matrix reduced by *p?gebrd*.

Constraints: $k \geq 0$.

a

(local)

COMPLEX for *psormbr*

DOUBLE COMPLEX for *pdormbr*.

Pointer into the local memory to an array of size $(l1d_a, LOCc(ja + \min(nq, k) - 1))$ if *vect*='Q', and $(l1d_a, LOCc(ja+nq-1))$ if *vect* = 'P'.

$nq = m$ if *side* = 'L', and $nq = n$ otherwise.

The vectors that define the elementary reflectors *H(i)* and *G(i)*, whose products determine the matrices *Q* and *P*, as returned by *p?gebrd*.

If *vect* = 'Q', $l1d_a \geq \max(1, LOCr(ia+nq-1))$;

If *vect* = 'P', $l1d_a \geq \max(1, LOCr(ia+\min(nq, k)-1))$.

ia, ja

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

COMPLEX for *pcunmbr*

DOUBLE COMPLEX for *pzunmbr*.

Array of size $LOCc(ja+\min(nq, k)-1)$, if *vect* = 'Q', and $LOCr(ia + \min(nq, k) - 1)$, if *vect* = 'P'.

tau(i) must contain the scalar factor of the elementary reflector *H(i)* or *G(i)*, which determines *Q* or *P*, as returned by *p?gebrd* in its array argument *tauq* or *taup*. *tau* is tied to the distributed matrix *A*.

c

(local) COMPLEX for *pcunmbr*

DOUBLE COMPLEX for *pzunmbr*

Pointer into the local memory to an array of size $(l1d_c, LOCc(jc+n-1))$.

Contains the local pieces of the distributed matrix sub (*C*).

ic, jc

(global) INTEGER. The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

COMPLEX for pcunmbr

DOUBLE COMPLEX for pzunmbr.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER, size of *work*, must be at least:

If *side* = 'L'

nq = *m*;

if ((*vect* = 'Q' and $nq \geq k$) or (*vect* is not equal to 'Q' and $nq > k$)), *iaa*= *ia*; *jaa*= *ja*; *mi*= *m*; *ni*= *n*; *icc*= *ic*; *jcc*= *jc*;

else

iaa= *ia*+1; *jaa*= *ja*; *mi*= *m*-1; *ni*= *n*; *icc*= *ic*+1; *jcc*= *jc*;

end if

else

If *side* = 'R', *nq* = *n*;

if ((*vect* = 'Q' and $nq \geq k$) or (*vect* is not equal to 'Q' and $nq > k$)),

iaa= *ia*; *jaa*= *ja*; *mi*= *m*; *ni*= *n*; *icc*= *ic*; *jcc*= *jc*;

else

iaa= *ia*; *jaa*= *ja*+1; *mi*= *m*; *ni*= *n*-1; *icc*= *ic*; *jcc*= *jc*+1;

end if

end if

If *vect* = 'Q',

If *side* = 'L', $lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a) + nb_a*nb_a$

else if *side* = 'R',

$lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0 + \max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a$

end if

else if *vect* is not equal to 'Q',

if *side* = 'L',

$lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 + \max(mqa0+numroc(numroc(mi+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmq), nqc0))*mb_a) + mb_a*mb_a$

else if *side* = 'R',

$lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a$

end if

end if

where *lcmp* = *lcm*/NPROW, *lcmq* = *lcm*/NPCOL, with *lcm* = *ilcm*(NPROW, NPCOL),

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(jaa, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(mi+icoffa, nb_a, MYCOL, iacol, NPCOL),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	On exit, if <code>vect='Q'</code> , <code>sub(C)</code> is overwritten by $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$; if <code>vect='P'</code> , <code>sub(C)</code> is overwritten by $P \cdot \text{sub}(C)$, or $P' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot P$, or $\text{sub}(C) \cdot P'$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Generalized Symmetric-Definite Eigen Problems

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScaLAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	<code>p?sygst</code>	<code>p?hegst</code>

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pssygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
call pdsygst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

Include Files

Description

The `p?sygst` routine reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$ and `sub(B)` denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If `ibtype = 1`, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and `sub(A)` is overwritten by $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$.

If `ibtype = 2` or `3`, the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and `sub(A)` is overwritten by $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$.

`sub(B)` must have been previously factorized as U^T*U or $L*L^T$ by `p?potrf`.

Input Parameters

<code>ibtype</code>	(global) INTEGER. Must be 1 or 2 or 3. If <code>ibtype = 1</code> , compute $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$; If <code>ibtype = 2</code> or <code>3</code> , compute $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$.
<code>uplo</code>	(global) CHARACTER. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , the upper triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as U^T*U . If <code>uplo = 'L'</code> , the lower triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as $L*L^T$.
<code>n</code>	(global) INTEGER. The order of the matrices <code>sub(A)</code> and <code>sub(B)</code> ($n \geq 0$).
<code>a</code>	(local) REAL for <code>pssygst</code> DOUBLE PRECISION for <code>pdsygst</code> .

Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. On entry, the array contains the local pieces of the n -by- n symmetric distributed matrix $sub(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

b

(local)

REAL for pssygst

DOUBLE PRECISION for pdsygst.

Pointer into the local memory to an array of size $(lld_b, LOCC(jb+n-1))$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $sub(B)$ as returned by `p?potrf`.

ib, jb

(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .

Output Parameters

a

On exit, if $info = 0$, the transformed matrix, stored in the same format as $sub(A)$.

scale

(global)

REAL for pssygst

DOUBLE PRECISION for pdsygst.

Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, *scale* is always returned as 1.0, it is returned here to allow for future enhancement.

info

(global) INTEGER.

If $info = 0$, the execution is successful. If $info < 0$, if the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?hegst

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pchegst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
call pzhegst(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale, info)
```

Include Files**Description**

The `p?hegst` routine reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$ and `sub(B)` denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If `ibtype = 1`, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and `sub(A)` is overwritten by $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$.

If `ibtype = 2` or `3`, the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and `sub(A)` is overwritten by $U*\text{sub}(A)*U^H$, or $L^H*\text{sub}(A)*L$.

`sub(B)` must have been previously factorized as U^H*U or $L*L^H$ by `p?potrf`.

Input Parameters

<code>ibtype</code>	(global) INTEGER. Must be 1 or 2 or 3. If <code>itype = 1</code> , compute $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$; If <code>itype = 2</code> or <code>3</code> , compute $U*\text{sub}(A)*U^H$, or $L^H*\text{sub}(A)*L$.
<code>uplo</code>	(global) CHARACTER. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , the upper triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as U^H*U . If <code>uplo = 'L'</code> , the lower triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as $L*L^H$.
<code>n</code>	(global) INTEGER. The order of the matrices <code>sub(A)</code> and <code>sub(B)</code> ($n \geq 0$).
<code>a</code>	(local) COMPLEX for <code>pchegst</code> DOUBLE COMPLEX for <code>pzhegst</code> . Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. On entry, the array contains the local pieces of the n -by- n Hermitian distributed matrix <code>sub(A)</code> . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) <code>COMPLEX</code> for <code>pchegst</code> <code>DOUBLE COMPLEX</code> for <code>pzhegst</code> . Pointer into the local memory to an array of size <code>(lld_b, LOcc(jb+n-1))</code> . On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (<i>B</i>) as returned by <code>p?potrf</code> .
<i>ib, jb</i>	(global) <code>INTEGER</code> . The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) <code>INTEGER</code> array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) <code>REAL</code> for <code>pchegst</code> <code>DOUBLE PRECISION</code> for <code>pzhegst</code> . Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) <code>INTEGER</code> . If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = <code>-(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = <code>-i</code> .

Driver Routines

Table "ScaLAPACK Driver Routines" lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	<code>p?gesv</code> (simple driver) / <code>p?gesvx</code> (expert driver)

Type of Problem	Matrix type, storage scheme	Driver
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) / p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general m -by- n	p?gels
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev / p?heev (simple driver); p?syevd / p?heevd (simple driver with a divide and conquer algorithm); p?syevx / p?heevx (expert driver); p?syevr / p?heevr (simple driver with MRRR algorithm)
Singular value decomposition	general m -by- n	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

[p?gesv](#)

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```
call psgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Include Files

Description

The `p?gesv` routine computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

n (global) `INTEGER`. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

$nrhs$ (global) `INTEGER`. The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).

a, b (local)

REAL for psgesv
 DOUBLE PRECISION for pdgesv
 COMPLEX for pcgesv
 DOUBLE COMPLEX for pzgesv.

Pointers into the local memory to arrays of local size $a(lld_a, LOCc(ja + n - 1))$ and $b(lld_b, LOCc(jb + nrhs - 1))$, respectively.

On entry, the array a contains the local pieces of the n -by- n distributed matrix sub(A) to be factored.

On entry, the array b contains the right hand side distributed matrix sub(B).

ia, ja (global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of sub(A), respectively.

$desca$ (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

ib, jb (global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of sub(B), respectively.

$descb$ (global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .

Output Parameters

a Overwritten by the factors L and U from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of L are not stored .

b Overwritten by the solution distributed matrix X .

$ipiv$ (local) INTEGER Array of size $LOCr(m_a) + mb_a$. This array contains the pivoting information. The (local) row i of the matrix was interchanged with the (global) row $ipiv(i)$.

This array is tied to the distributed matrix A .

$info$ (global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i * 100 + j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gesvx

Uses the LU factorization to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

```
call psgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work, lwork,
iwork, liwork, info)
```

```
call pdgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work, lwork,
iwork, liwork, info)
```

```
call pcgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,

rwork, lrwork, info)
```

Include Files

Description

The p?gesvx routine uses the LU factorization to compute the solution to a real or complex system of linear equations $AX = B$, where A denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, B denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and X denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, af stands for the subarray $af(iaf:iaf+n-1, jaf:jaf+n-1)$.

The routine p?gesvx performs the following steps:

1. If $fact = 'E'$, real scaling factors R and C are computed to equilibrate the system:

```
trans = 'N': diag(R)*A*diag(C) *diag(C)-1*X = diag(R)*B
```

```
trans = 'T': (diag(R)*A*diag(C))T *diag(R)-1*X = diag(C)*B
```

```
trans = 'C': (diag(R)*A*diag(C))H *diag(R)-1*X = diag(C)*B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if $trans = 'N'$) or $\text{diag}(C) * B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = PLU$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $trans = 'N'$) or $\text{diag}(R)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

<i>fact</i>	<p>(global) CHARACTER*1. Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix <i>A</i> is supplied on entry, and if not, whether the matrix <i>A</i> should be equilibrated before it is factored.</p> <p>If <i>fact</i> = 'F' then, on entry, <i>af</i> and <i>ipiv</i> contain the factored form of <i>A</i>. If <i>equed</i> is not 'N', the matrix <i>A</i> has been equilibrated with scaling factors given by <i>r</i> and <i>c</i>. Arrays <i>a</i>, <i>af</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix <i>A</i> is copied to <i>af</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix <i>A</i> is equilibrated if necessary, then copied to <i>af</i> and factored.</p>
<i>trans</i>	<p>(global) CHARACTER*1. Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A*X = B$ (No transpose);</p> <p>If <i>trans</i> = 'T', the system has the form $A^T*X = B$ (Transpose);</p> <p>If <i>trans</i> = 'C', the system has the form $A^H*X = B$ (Conjugate transpose);</p>
<i>n</i>	<p>(global) INTEGER. The number of linear equations; the order of the submatrix <i>A</i> ($n \geq 0$).</p>
<i>nrhs</i>	<p>(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrices <i>B</i> and <i>X</i> ($nrhs \geq 0$).</p>
<i>a</i> , <i>af</i> , <i>b</i> , <i>work</i>	<p>(local)</p> <p>REAL for psgesvx</p> <p>DOUBLE PRECISION for pdgesvx</p> <p>COMPLEX for pcgesvx</p> <p>DOUBLE COMPLEX for pzgesvx.</p> <p>Pointers into the local memory to arrays of local size $a(lld_a, LOCC(ja+n-1))$, $af(lld_af, LOCC(ja+n-1))$, $b(lld_b, LOCC(jb+nrhs-1))$, $work(lwork)$.</p> <p>The array <i>a</i> contains the matrix <i>A</i>. If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i>.</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. In this case it contains on entry the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P*L*U$ as computed by p?getrf. If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix <i>A</i>.</p> <p>The array <i>b</i> contains on entry the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> <p><i>work</i> is a workspace array. The size of <i>work</i> is (<i>lwork</i>).</p>
<i>ia</i> , <i>ja</i>	<p>(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.</p>

<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the subarray <i>af(iaf:iaf+n-1, jaf:jaf+n-1)</i> , respectively.
<i>descaf</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B(ib:ib+n-1, jb:jb+nrhs-1)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ipiv</i>	<p>(local) INTEGER Array of size <i>LOCr(m_a)+mb_a</i>.</p> <p>The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F' .</p> <p>On entry, it contains the pivot indices from the factorization $A = P^*L^*U$ as computed by <code>p?getrf</code>; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv(i)</i>.</p> <p>This array must be aligned with <i>A(ia:ia+n-1, *)</i>.</p>
<i>equed</i>	<p>(global) CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F' . It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N');</p> <p>If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag(r)</i>;</p> <p>If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i>;</p> <p>If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by <i>diag(r)*A*diag(c)</i>.</p>
<i>r, c</i>	<p>(local) REAL for single precision flavors;</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Arrays of size <i>LOCr(m_a)</i> and <i>LOCc(n_a)</i>, respectively.</p> <p>The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag(r)</i>; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag(c)</i>; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p>

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive. Array *r* is replicated in every process column, and is aligned with the distributed matrix *A*. Array *c* is replicated in every process row, and is aligned with the distributed matrix *A*.

<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the submatrix <i>X(ix:ix+n-1, jx:jx+nrhs-1)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> ; must be at least $\max(\text{p?gecon}(lwork), \text{p?gerfs}(lwork)) + LOCr(n_a)$.
<i>iwork</i>	(local, psgesvx/pdgesvx only) INTEGER. Workspace array. The size of <i>iwork</i> is (<i>liwork</i>).
<i>liwork</i>	(local, psgesvx/pdgesvx only) INTEGER. The size of the array <i>iwork</i> , must be at least <i>LOCr(n_a)</i> .
<i>rwork</i>	(local) REAL for pcgesvx DOUBLE PRECISION for pzgesvx. Workspace array, used in complex flavors only. The size of <i>rwork</i> is (<i>lrwork</i>).
<i>lrwork</i>	(local or global, pcgesvx/pzgesvx only) INTEGER. The size of the array <i>rwork</i> ; must be at least $2 * LOCc(n_a)$.

Output Parameters

<i>x</i>	(local) REAL for psgesvx DOUBLE PRECISION for pdgesvx COMPLEX for pcgesvx DOUBLE COMPLEX for pzgesvx. Pointer into the local memory to an array of local size $x(lld_x, LOCc(jx + nrhs - 1))$. If <i>info</i> = 0, the array <i>x</i> contains the solution matrix <i>X</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the <i>equilibrated</i> system is: $\text{diag}(C) - 1 * X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; and $\text{diag}(R) - 1 * X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.
<i>a</i>	Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>equed</i> ≠ 'N', <i>A</i> is scaled on exit as follows: <i>equed</i> = 'R': $A = \text{diag}(R) * A$

	$equed = 'C': A = A * \text{diag}(c)$ $equed = 'B': A = \text{diag}(R) * A * \text{diag}(c)$
<i>af</i>	If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>a</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $\text{diag}(R) * B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $\text{diag}(c) * B$ if <i>trans</i> = 'T' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.
<i>r, c</i>	These arrays are output arguments if <i>fact</i> ≠ 'F'. See the description of <i>r, c</i> in <i>Input Arguments</i> section.
<i>rcond</i>	(global)REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>ferr, berr</i>	(local)REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays of size <i>LOCc</i> (<i>n_b</i>) each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector. Arrays <i>ferr</i> and <i>berr</i> are both replicated in every process row, and are aligned with the matrices <i>B</i> and <i>X</i> .
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) returns the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	If <i>info</i> =0, on exit <i>iwork</i> (1) returns the minimum value of <i>liwork</i> required for optimum performance.
<i>rwork</i> (1)	If <i>info</i> =0, on exit <i>rwork</i> (1) returns the minimum value of <i>lrwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful.

$info < 0$: if the i th argument is an array and the j th entry had an illegal value, then $info = -(i*100+j)$; if the i th argument is a scalar and had an illegal value, then $info = -i$. If $info = i$, and $i \leq n$, then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

p?gbsv

Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.

Syntax

```
call psgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pdgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pcgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
call pzgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork, info)
```

Include Files

Description

The `p?gbsv` routine computes the solution to a real or complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U * Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of subdiagonals within the band of <i>A</i> ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed matrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>a, b</i>	<p>(local)</p> <p>REAL for psgbsv</p> <p>DOUBLE PRECISION for pdgbsv</p> <p>COMPLEX for pcgbsv</p> <p>DOUBLE COMPLEX for pzgbsv.</p> <p>Pointers into the local memory to arrays of local size $a(lld_a, LOCC(ja + n - 1))$ and $b(lld_b, LOCC(nrhs))$.</p> <p>On entry, the array <i>a</i> contains the local pieces of the global array <i>A</i>.</p> <p>On entry, the array <i>b</i> contains the right hand side distributed matrix sub(<i>B</i>).</p>
<i>ja</i>	(global) INTEGER. The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p> <p>If $desca(dtype_)$ = 501, then $dlen_ \geq 7$;</p> <p>else if $desca(dtype_)$ = 1, then $dlen_ \geq 9$.</p>
<i>ib</i>	(global) INTEGER. The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	<p>(global and local) INTEGER array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>B</i>.</p> <p>If $descb(dtype_)$ = 502, then $dlen_ \geq 7$;</p> <p>else if $descb(dtype_)$ = 1, then $dlen_ \geq 9$.</p>
<i>work</i>	<p>(local)</p> <p>REAL for psgbsv</p> <p>DOUBLE PRECISION for pdgbsv</p> <p>COMPLEX for pcgbsv</p> <p>DOUBLE COMPLEX for pzgbsv.</p>

Workspace array of size *lwork*.

lwork (local or global) INTEGER. The size of the array *work*, must be at least $lwork \geq (NB+bwu) * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2 * bwu) +$
 $+ \max(nrhs * (NB+2 * bwl+4 * bwu), 1).$

Output Parameters

a On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

b On exit, this array contains the local pieces of the solution distributed matrix *X*.

ipiv (local) INTEGER array.
 The size of *ipiv* must be at least *desca*(NB). This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*.
info > 0:
 If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbsv

Solves a general band system of linear equations.

Syntax

```
call psdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pddbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The `p?dbsv` routine solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl, bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix A , ($n \geq 0$).
bwl	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
bwu	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
$nrhs$	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$).
a	(local). REAL for <code>psdbsv</code> DOUBLE PRECISION for <code>pddbsv</code> COMPLEX for <code>pcdbsv</code> DOUBLE COMPLEX for <code>pzdbsv</code> . Pointer into the local memory to an array with leading size $lld_a \geq (bwl + bwu + 1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix.
ja	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) INTEGER array of size $dlen$. If 1d type ($dtype_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
b	(local)

REAL for psdbsv
 DOUBLE PRECISION for pddbsv
 COMPLEX for pcdbsv
 DOUBLE COMPLEX for pzdbsv.

Pointer into the local memory to an array of local lead size $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.

ib (global) INTEGER. The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).

descb (global and local) INTEGER array of size $dlen$.
 If 1d type ($dtype_b = 502$), $dlen \geq 7$;
 If 2d type ($dtype_b = 1$), $dlen \geq 9$.
 The array descriptor for the distributed matrix B .
 Contains information of mapping of B to memory.

work (local).
 REAL for psdbsv
 DOUBLE PRECISION for pddbsv
 COMPLEX for pcdbsv
 DOUBLE COMPLEX for pzdbsv.
 Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.
 $lwork \geq nb(bwl + bwu) + 6 \max(bwl, bwu) * \max(bwl, bwu) + \max((\max(bwl, bwu) nrhs), \max(bwl, bwu) * \max(bwl, bwu))$

Output Parameters

a On exit, this array contains information containing details of the factorization.

Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b On exit, this contains the local piece of the solutions distributed matrix X .

work On exit, *work*(1) contains the minimal *lwork*.

info (local) INTEGER. If *info*=0, the execution is successful.
 < 0 : If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0 : If $info = k < NPROCS$, the submatrix stored on processor $info$ and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not positive definite, and the factorization was not completed.

p?dtsv

Solves a general tridiagonal system of linear equations.

Syntax

```
call psdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pddtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pcdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pzdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Notice revision #20110804

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$).
dl	(local).REAL for psdtsv DOUBLE PRECISION for pddtsv

	<p>COMPLEX for pcdtsv</p> <p>DOUBLE COMPLEX for pzdtstv.</p> <p>Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $dl(1)$ is not referenced, and dl must be aligned with d. Must be of size $> desca(nb_)$.</p>
d	<p>(local). REAL for psdtsv</p> <p>DOUBLE PRECISION for pddtsv</p> <p>COMPLEX for pcdtsv</p> <p>DOUBLE COMPLEX for pzdtstv.</p> <p>Pointer to local part of global vector storing the main diagonal of the matrix.</p>
du	<p>(local). REAL for psdtsv</p> <p>DOUBLE PRECISION for pddtsv</p> <p>COMPLEX for pcdtsv</p> <p>DOUBLE COMPLEX for pzdtstv.</p> <p>Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d.</p>
ja	<p>(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p>
$desca$	<p>(global and local) INTEGER array of size $dlen$.</p> <p>If 1d type ($dtype_a=501$ or 502), $dlen \geq 7$;</p> <p>If 2d type ($dtype_a=1$), $dlen \geq 9$.</p> <p>The array descriptor for the distributed matrix A.</p> <p>Contains information of mapping of A to memory.</p>
b	<p>(local)</p> <p>REAL for psdtsv</p> <p>DOUBLE PRECISION for pddtsv</p> <p>COMPLEX for pcdtsv</p> <p>DOUBLE COMPLEX for pzdtstv.</p> <p>Pointer into the local memory to an array of local lead size $lld_b > nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.</p>
ib	<p>(global) INTEGER. The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).</p>
$descb$	<p>(global and local) INTEGER array of size $dlen$.</p> <p>If 1d type ($dtype_b=502$), $dlen \geq 7$;</p> <p>If 2d type ($dtype_b=1$), $dlen \geq 9$.</p>

The array descriptor for the distributed matrix B .
Contains information of mapping of B to memory.

work

(local).

REAL for psdtsv

DOUBLE PRECISION for pddtsv

COMPLEX for pcdtsv

DOUBLE COMPLEX for pzdtsv. Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork

(local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. $lwork > (12 * NPCOL + 3 * nb) + \max((10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs, 8 * NPCOL)$

Output Parameters

dl

On exit, this array contains information containing the * factors of the matrix.

d

On exit, this array contains information containing the * factors of the matrix. Must be of size $> desca(nb_)$.

du

On exit, this array contains information containing the * factors of the matrix. Must be of size $> desca(nb_)$.

b

On exit, this contains the local piece of the solutions distributed matrix X .

work

On exit, *work*(1) contains the minimal *lwork*.

info

(local) INTEGER. If *info*=0, the execution is successful.

< 0 : If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0 : If $info = k < NPROCS$, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not positive definite, and the factorization was not completed.

call pzposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Include Files

Description

The `p?posv` routine computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor $\text{sub}(A)$ as

$$\text{sub}(A) = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of $\text{sub}(A)$ is then used to solve the system of equations.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a</i>	(local) REAL for <code>psposv</code> DOUBLE PRECISION for <code>pdposv</code> COMPLEX for <code>pcposv</code> COMPLEX*16 for <code>pzposv</code> . Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$ to be factored. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for <i>psposv</i> DOUBLE PRECISION for <i>pdposv</i> COMPLEX for <i>pcposv</i> COMPLEX*16 for <i>pzposv</i> . Pointer into the local memory to an array of size $(l1d_b, LOCc(jb + nrhs - 1))$. On entry, the local pieces of the right hand sides distributed matrix <i>sub(B)</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, this array contains the local pieces of the factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $L * L^H$.
<i>b</i>	On exit, if <i>info</i> = 0, <i>sub(B)</i> is overwritten by the solution distributed matrix <i>X</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> > 0: If <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> , $A(ia:ia+k-1, ja:ja+k-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed.

liwork, info)
```

Include Files

Description

The `p?posvx` routine uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$, an m -by- k matrix where y can be a, af, b and x .

The routine `p?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(sr) * A * \text{diag}(sc) * \text{inv}(\text{diag}(sc)) * X = \text{diag}(sr) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(sr) * A * \text{diag}(sc)$ and B by $\text{diag}(sr) * B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(sr)$ so that it solves the original system before equilibration.

Input Parameters

`fact` (global) CHARACTER. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, af contains the factored form of A . If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s . a and af will not be modified.

If $fact = 'N'$, the matrix A will be copied to af and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.

$uplo$

(global) CHARACTER. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored.

n

(global) INTEGER. The order of the distributed matrix sub(A) ($n \geq 0$).

$nrhs$

(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrices B and X . ($nrhs \geq 0$).

a

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size ($lld_a, LOCC(ja + n - 1)$). On entry, the symmetric/Hermitian matrix A , except if $fact = 'F'$ and $equed = 'Y'$, then A must contain the equilibrated matrix $diag(sr) * A * diag(sc)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. A is not modified if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$ on exit.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

af

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

Pointer into the local memory to an array of local size ($lld_af, LOCC(ja + n - 1)$).

If $fact = 'F'$, then af is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A . If $equed \neq 'N'$, then af is the factored form of the equilibrated matrix $diag(sr) * A * diag(sc)$.

iaf, jaf

(global) INTEGER. The row and column indices in the global matrix AF indicating the first row and the first column of the submatrix AF , respectively.

$descaf$

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix AF .

$equed$

(global) CHARACTER. Must be 'N' or 'Y'.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);

If $equed = 'Y'$, equilibration was done and A has been replaced by $diag(sr) * A * diag(sc)$.

sr

(local)

REAL for $psposvx$

DOUBLE PRECISION for $pdposvx$

COMPLEX for $pcposvx$

DOUBLE COMPLEX for $pzposvx$.

Array of size lld_a .

The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $equed = 'N'$, s is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

b

(local)

REAL for $psposvx$

DOUBLE PRECISION for $pdposvx$

COMPLEX for $pcposvx$

DOUBLE COMPLEX for $pzposvx$.

Pointer into the local memory to an array of local size $(lld_b, LOCC(jb + nrhs - 1))$. On entry, the n -by- $nrhs$ right-hand side matrix B .

ib, jb

(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

$descb$

(global and local) INTEGER. Array of size $dlen_$. The array descriptor for the distributed matrix B .

x

(local)

REAL for $psposvx$

DOUBLE PRECISION for `pdposvx`

COMPLEX for `pcposvx`

DOUBLE COMPLEX for `pzposvx`.

Pointer into the local memory to an array of local size $(l1d_x, LOCc(jx + nrhs - 1))$.

ix, jx

(global) INTEGER. The row and column indices in the global matrix X indicating the first row and the first column of the submatrix X , respectively.

descx

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix X .

work

(local)

REAL for `psposvx`

DOUBLE PRECISION for `pdposvx`

COMPLEX for `pcposvx`

DOUBLE COMPLEX for `pzposvx`.

Workspace array of size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work*. *lwork* is local input and must be at least $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + LOCr(n_a)$.

$lwork = 3 * desca(l1d_)$.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork

(local) INTEGER. Workspace array of size *liwork*.

liwork

(local or global)

INTEGER. The size of the array *iwork*. *liwork* is local input and must be at least $liwork = desca(l1d_)$ $liwork = LOCr(n_a)$.

If $liwork = -1$, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, if *fact* = 'E' and *equed* = 'Y', *a* is overwritten by $diag(sr) * a * diag(sc)$.

af

If *fact* = 'N', then *af* is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix A .

If $fact = 'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

equed

If $fact \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

sr

This array is an output argument if $fact \neq 'F'$.

See the description of *sr* in *Input Arguments* section.

sc

This array is an output argument if $fact \neq 'F'$.

See the description of *sc* in *Input Arguments* section.

b

On exit, if *equed* = 'N', *b* is not modified; if *trans* = 'N' and *equed* = 'R' or 'B', *b* is overwritten by $\text{diag}(r) * b$; if *trans* = 'T' or 'C' and *equed* = 'C' or 'B', *b* is overwritten by $\text{diag}(c) * b$.

x

(local)

REAL for psposvx

DOUBLE PRECISION for pdposvx

COMPLEX for pcposvx

DOUBLE COMPLEX for pzposvx.

If *info* = 0 the *n*-by-*nrhs* solution matrix *X* to the original system of equations.

Note that *A* and *B* are modified on exit if *equed* \neq 'N', and the solution to the equilibrated system is

$\text{inv}(\text{diag}(sc)) * X$ if *trans* = 'N' and *equed* = 'C' or 'B', or

$\text{inv}(\text{diag}(sr)) * X$ if *trans* = 'T' or 'C' and *equed* = 'R' or 'B'.

rcond

(global)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision (in particular, if *rcond*=0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays of size at least $\max(LOC, n_b)$. The estimated forward error bounds for each solution vector *X*(*j*) (the *j*-th column of the solution matrix *X*). If *xtrue* is the true solution, *ferr*(*j*) bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest entry in

$X(j)$. The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed.

berr

(local)

REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays of size at least $\max(LOC, n_b)$. The componentwise relative backward error of each solution vector $X(j)$ (the smallest relative change in any entry of A or B that makes $X(j)$ an exact solution).

work(1)

(local) On exit, *work(1)* returns the minimal and optimal *liwork*.

info

(global) INTEGER.

If *info*=0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: if *info* = *i*, and *i* is $\leq n$: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

```
call pcpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

```
call pzpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The p?pbsv routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth *bw*.

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

p?ptsv

Syntax

Solves a symmetric or Hermitian positive definite tridiagonal system of linear equations.

```
call psptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pdptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pcptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pzptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
```

Include Files

Description

The `p?ptsv` routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real tridiagonal symmetric positive definite distributed matrix.

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

Notice revision #20110804

Input Parameters

n	(global) INTEGER. The order of matrix A ($n \geq 0$).
$nrhs$	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
d	(local) REAL for <code>psptsv</code> DOUBLE PRECISION for <code>pdptsv</code> COMPLEX for <code>pcptsv</code> DOUBLE COMPLEX for <code>pzptsv</code> . Pointer to local part of global vector storing the main diagonal of the matrix.
e	(local) REAL for <code>psptsv</code> DOUBLE PRECISION for <code>pdptsv</code> COMPLEX for <code>pcptsv</code> DOUBLE COMPLEX for <code>pzptsv</code> .

	Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d .
<i>ja</i>	(global) INTEGER. The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array of size $dlen$. If 1d type ($dtype_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
<i>b</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer into the local memory to an array of local lead size $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).
<i>descb</i>	(global and local) INTEGER array of size $dlen$. If 1d type ($dtype_b = 502$), $dlen \geq 7$; If 2d type ($dtype_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix B . Contains information of mapping of B to memory.
<i>work</i>	(local). REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned. $lwork > (12 * NPCOL + 3 * nb) + \max((10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs, 8 * NPCOL)$.

Output Parameters

<i>d</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca(nb_)</i> .
<i>e</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca(nb_)</i> .
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i>	On exit, <i>work(1)</i> contains the minimal <i>lwork</i> .
<i>info</i>	<p>(local) INTEGER. If <i>info</i>=0, the execution is successful.</p> <p>< 0: If the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.</p> <p>> 0: If <i>info</i> = $k \leq \text{NPROCS}$, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed.</p> <p>If <i>info</i> = $k > \text{NPROCS}$, the submatrix stored on processor <i>info</i>-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.</p>

p?gels

Solves overdetermined or underdetermined linear systems involving a matrix of full rank.

Syntax

```
call psgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pdgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pcgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
call pzgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

Include Files

Description

The *p?gels* routine solves overdetermined or underdetermined real/ complex linear systems involving an *m*-by-*n* matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If *trans* = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||\text{sub}(B) - \text{sub}(A)*X||$$
2. If *trans* = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $\text{sub}(A)*X = \text{sub}(B)$.

3. If $trans = 'T'$ and $m \geq n$: find the minimum norm solution of an undetermined system $sub(A)^T X = sub(B)$.
4. If $trans = 'T'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||sub(B) - sub(A)^T X||,$$

where $sub(B)$ denotes $B(ib:ib+m-1, jb:jb+nrhs-1)$ when $trans = 'N'$ and $B(ib:ib+n-1, jb:jb+nrhs-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when $trans = 'N'$, the solution vectors are stored as the columns of the n -by- $nrhs$ right hand side matrix $sub(B)$ and the m -by- $nrhs$ right hand side matrix $sub(B)$ otherwise.

Input Parameters

<i>trans</i>	(global) CHARACTER. Must be 'N', or 'T'. If $trans = 'N'$, the linear system involves matrix $sub(A)$; If $trans = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only).
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $sub(A)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $sub(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in the distributed submatrices $sub(B)$ and X . ($nrhs \geq 0$).
<i>a</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Pointer into the local memory to an array of size $(lld_a, LOCC(ja+n-1))$. On entry, contains the m -by- n matrix A .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels.

Pointer into the local memory to an array of local size $(lld_b, LOCC(jb + nrhs - 1))$. On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; $sub(B)$ is m -by- $nrhs$ if $trans = 'N'$, and n -by- $nrhs$ otherwise.

ib, jb

(global) INTEGER. The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix B .

work

(local)

REAL for psgels

DOUBLE PRECISION for pdgels

COMPLEX for pcgels

DOUBLE COMPLEX for pzgels.

Workspace array with size *lwork*.

lwork

(local or global) INTEGER.

The size of the array *work/lwork* is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then

```
ltau = numroc(ja+min(m,n)-1, nb_a, MYCOL, csrc_a, NPCOL),
```

```
lwf = nb_a*(mpa0 + nqa0 + nb_a)
```

```
lws = max((nb_a*(nb_a-1))/2, (nrhsqb0 + mpb0)*nb_a) +
nb_a*nb_a
```

```
else
```

```
ltau = numroc(ia+min(m,n)-1, mb_a, MYROW, rsrc_a, NPROW),
```

```
lwf = mb_a * (mpa0 + nqa0 + mb_a)
```

```
lws = max((mb_a*(mb_a-1))/2, (npb0 + max(nqa0 +
numroc(numroc(n+iroffba, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nrhsqb0))*mb_a) + mb_a*mb_a
```

```
end if,
```

where $lcmp = lcm/NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,

```
iroffba = mod(ia-1, mb_a),
```

```
icoffba = mod(ja-1, nb_a),
```

```
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
```

```
iacol = indxg2p(ja, nb_a, MYROW, rsrc_a, NPROW)
```

```
mpa0 = numroc(m+iroffba, mb_a, MYROW, iarow, NPROW),
```

```
nqa0 = numroc(n+icoffba, nb_a, MYCOL, iacol, NPCOL),
```

```
iroffba = mod(ib-1, mb_b),
```

```
icoffba = mod(jb-1, nb_b),
```

```
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
```

```

ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW`, and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, If $m \geq n$, <code>sub(A)</code> is overwritten by the details of its <i>QR</i> factorization as returned by <code>p?geqrf</code> ; if $m < n$, <code>sub(A)</code> is overwritten by details of its <i>LQ</i> factorization as returned by <code>p?gelqf</code> .
<i>b</i>	On exit, <code>sub(B)</code> is overwritten by the solution vectors, stored columnwise: if $trans = 'N'$ and $m \geq n$, rows 1 to n of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column; If $trans = 'N'$ and $m < n$, rows 1 to n of <code>sub(B)</code> contain the minimum norm solution vectors; If $trans = 'T'$ and $m \geq n$, rows 1 to m of <code>sub(B)</code> contain the minimum norm solution vectors; if $trans = 'T'$ and $m < n$, rows 1 to m of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
call pssyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
call pdsyev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, info)
```

Include Files

Description

The `p?syev` routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK routines.

In its present form, the routine assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) CHARACTER. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).
<i>a</i>	(local) REAL for <code>pssyev</code> . DOUBLE PRECISION for <code>pdsyev</code> . Block cyclic array of global size (n, n) and local size $(l1d_a, LOCC(ja + n - 1))$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) REAL for pssyev. DOUBLE PRECISION for pdsyev. Array of size <i>lwork</i> .
<i>lwork</i>	(local) INTEGER. See below for definitions of variables used to define <i>lwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then $lwork \geq 5*n + sizesytrd + 1$, where <i>sizesytrd</i> is the workspace for <i>p?sytrd</i> and is $\max(NB*(np + 1), 3*NB)$. If eigenvectors are requested (<i>jobz</i> = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is: $qrmem = 2*n-2$ $lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$ <p>Variable definitions:</p> $nb = desca(mb_) = desca(nb_) = descz(mb_) = descz(nb_);$ $nn = \max(n, nb, 2);$ $desca(rsrc_) = desca(rsrc_) = descz(rsrc_) = descz(csrc_) = 0$ $np = \text{numroc}(nn, nb, 0, 0, NPROW)$ $nq = \text{numroc}(\max(n, nb, 2), nb, 0, 0, NPCOL)$ $nrc = \text{numroc}(n, nb, myprowc, 0, NPROCS)$ $ldc = \max(1, nrc)$ <p><i>sizemqrleft</i> is the workspace for <i>p?ormtr</i> when its <i>side</i> argument is 'L'. <i>myprowc</i> is defined when a new context is created as follows:</p> <pre>call blacs_get(desca(ctxt_), 0, contextc) call blacs_gridinit(contextc, 'R', NPROCS, 1) call blacs_gridinfo(contextc, nprowc, npcoldc, myprowc, mypcoldc)</pre> <p>If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i>.</p>

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). REAL for pssyev DOUBLE PRECISION for pdsyev Array of size <i>n</i> . On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for pssyev DOUBLE PRECISION for pdsyev Array, global size (<i>n</i> , <i>n</i>), local size (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> (1)	On output, <i>work</i> (1) returns the workspace needed to guarantee completion. If the input parameters are incorrect, <i>work</i> (1) may also be incorrect. If <i>jobz</i> = 'N' <i>work</i> (1) = minimal (optimal) amount of workspace If <i>jobz</i> = 'V' <i>work</i> (1) = minimal workspace required to generate all the eigenvectors.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge in ?steqr2 after a total of 30 <i>n</i> iterations. If <i>info</i> = <i>n</i> +1, then p?syevev has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?syevev cannot be guaranteed.

p?syevev

Computes all eigenvalues and eigenvectors of a real symmetric matrix by using a divide and conquer algorithm.

Syntax

```
call pssyevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
iwork, liwork, info)
```

```
call pdsyevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
iwork, liwork, info)
```

Include Files

Description

The `p?syevd` routine computes all eigenvalues and eigenvectors of a real symmetric matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).
<i>a</i>	(local). REAL for <code>pssyevd</code> DOUBLE PRECISION for <code>pdsyevd</code> . Block cyclic array of global size (n, n) and local size $(lld_a, LOCC(ja + n - 1))$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A . If <i>desca</i> (<i>ctxt_</i>) is incorrect, <code>p?syevd</code> cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

<i>descz</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i> .
<i>work</i>	(local). REAL for pssyevd DOUBLE PRECISION for pdsyevd. Array of size <i>lwork</i> .
<i>lwork</i>	(local) INTEGER. The size of the array <i>work</i> . If eigenvalues are requested: $lwork \geq \max(1 + 6*n + 2*np*nq, \text{trilwmin}) + 2*n$ with $\text{trilwmin} = 3*n + \max(nb*(np + 1), 3*nb)$ $np = \text{numroc}(n, nb, \text{myrow}, \text{iarrow}, \text{NPROW})$ $nq = \text{numroc}(n, nb, \text{mycol}, \text{iacol}, \text{NPCOL})$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxxerbla.
<i>iwork</i>	(local) INTEGER. Workspace array of size <i>liwork</i> .
<i>liwork</i>	(local) INTEGER, size of <i>iwork</i> . $liwork = 7*n + 8*npcol + 2.$

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for pssyevd DOUBLE PRECISION for pdsyevd. Array of size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local). REAL for pssyevd DOUBLE PRECISION for pdsyevd. Array, global size (<i>n</i> , <i>n</i>), local size (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> .
<i>work</i> (1)	On exit, returns adequate workspace to allow optimal performance.
<i>iwork</i> (1)	(local). On exit, if <i>liwork</i> > 0, <i>iwork</i> (1) returns the optimal <i>liwork</i> .

info (global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

The algorithm failed to compute the *info*/(*n*+1)-th eigenvalue while working on the submatrix lying in global rows and columns `mod(info,n+1)`.

NOTE

`mod(x,y)` is the integer remainder of *x*/*y*.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using Relatively Robust Representation.

Syntax

```
call pssyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
  iz, jz, descz, work, lwork, iwork, liwork, info )
```

```
call pdsyevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
  iz, jz, descz, work, lwork, iwork, liwork, info )
```

Include Files**Description**

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK routines.

First, the matrix *A* is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in *w*. The eigenvector matrix *z* is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

<i>iu</i>	<p>(global) INTEGER</p> <p>If <i>range</i>='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$.</p> <p>Not referenced if <i>range</i> = 'A'.</p>
<i>iz</i>	<p>(global) INTEGER</p> <p>Global row index in the global matrix <i>Z</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.</p>
<i>jz</i>	<p>(global) INTEGER</p> <p>Global column index in the global matrix <i>Z</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.</p>
<i>descz</i>	<p>INTEGER array of size <i>dlen_</i>.</p> <p>The array descriptor for the distributed matrix <i>z</i>.</p> <p>The context <i>descz</i>(<i>ctxt_</i>) must equal <i>desca</i>(<i>ctxt_</i>). Also note the array alignment requirements specified below.</p>
<i>work</i>	<p>REAL for <i>pssyevr</i></p> <p>DOUBLE PRECISION for <i>pdsyevr</i></p> <p>(local workspace) array of size <i>lwork</i></p>
<i>lwork</i>	<p>(local) INTEGER</p> <p>Size of <i>work</i>, must be at least 3.</p>

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lwork \geq 2 + 5*n + \max(12 * nn, neig * (np0 + 1))$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lwork \geq 2 + 5*n + \max(18*nn, np0 * mq0 + 2 * neig * neig) + (2 + \text{iceil}(neig, nprow*npcol))*nn$$

Variable definitions:

neig = number of eigenvectors requested

$$nb = \text{desca}(mb_) = \text{desca}(nb_) = \text{descz}(mb_) = \text{descz}(nb_)$$

$$nn = \max(n, neig, 2)$$

$$\text{desca}(rsrc_) = \text{desca}(csrc_nb_) = \text{descz}(rsrc_) = \text{descz}(csrc_) = 0$$

$$np0 = \text{numroc}(nn, neig, 0, 0, nprow)$$

$$mq0 = \text{numroc}(\max(neig, neig, 2), neig, 0, 0, npc0)$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*), and *nprow* and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*.

liwork

(local) INTEGER

size of *iwork*

Let *nnp* = max(*n*, *nprow*npcol* + 1, 4). Then:

$$liwork \geq 12*nnp + 2*n \text{ when the eigenvectors are desired}$$

$$liwork \geq 10*nnp + 2*n \text{ when only the eigenvalues have to be computed}$$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

OUTPUT Parameters

m

(global) INTEGER

Total number of eigenvalues found. $0 \leq m \leq n$.

nz

(global) INTEGER

Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m*

<i>w</i>	<p>REAL for pssyevr</p> <p>DOUBLE PRECISION for pdsyevr</p> <p>(global) array of size n</p> <p>Upon successful exit, the first m entries contain the selected eigenvalues in ascending order.</p>
<i>z</i>	<p>REAL for pssyevr</p> <p>DOUBLE PRECISION for pdsyevr</p> <p>Block-cyclic array, global size(n, n), local size ($lld_z, LOC_c(jz+n-1)$) .</p> <p>On exit, contains local pieces of distributed matrix Z.</p>
<i>work</i>	<p>On return, $work(1)$ contains the optimal amount of workspace required for efficient execution. If $jobz='N'$ $work(1)$ = optimal amount of workspace required to compute the eigenvalues. If $jobz='V'$ $work(1)$ = optimal amount of workspace required to compute eigenvalues and eigenvectors.</p>
<i>iwork</i>	<p>(local workspace) INTEGER array</p> <p>On return, $iwork(1)$ contains the amount of integer workspace required.</p>
<i>info</i>	<p>(global) INTEGER</p> <p>= 0: successful exit</p> <p>< 0: If the i-th argument is an array and the jth-entry had an illegal value, then $info = -(i*100+j)$, if the i-th argument is a scalar and had an illegal value, then $info = -i$.</p>

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $desca(m_) = descz(m_) = desca(n_) = descz(n_)$
2. Quadratic conformal blocking: $desca(mb_) = desca(nb_) = descz(mb_) = descz(nb_)$, $desca(rsrc_) = descz(rsrc_)$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

p?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

call pssyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)

```
call pdsyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz,
w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

Description

The `p?syevx` routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global) CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Block cyclic array of global size (<i>n</i> , <i>n</i>) and local size (<code>lld_a</code> , <code>LOCc(ja + n - 1)</code>). On entry, the symmetric matrix <i>A</i> .

If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the symmetric matrix.

If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the symmetric matrix.

ia, ja

(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .

vl, vu

(global)

REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if $range = 'A'$ or $'I'$.

il, iu

(global) INTEGER.

If $range = 'I'$, the indices of the smallest and largest eigenvalues to be returned.

Constraints: $il \geq 1$

$\min(il, n) \leq iu \leq n$

Not referenced if $range = 'A'$ or $'V'$.

$abstol$

(global).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

If $jobz = 'V'$, setting $abstol$ to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$abstol + eps * \max(|a|, |b|)$,

where eps is the machine precision. If $abstol$ is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $(\text{mod}(info, 2) \neq 0)$ or $(\text{mod}(info/8, 2) \neq 0)$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * p?lamch('S')$.

$orfac$

(global).REAL for pssyevx

DOUBLE PRECISION for pdsyevx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient

(see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

REAL for *pssyevx*.

DOUBLE PRECISION for *pdsyevx*.

Array of size *lwork*.

lwork

(local) INTEGER. The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{iceil}(neig, NPROW*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac*2*norm(A)\},$$

where

neig = number of eigenvectors requested

nb = *desca(mb_)* = *desca(nb_)* = *descz(mb_)* = *descz(nb_)*;

nn = $\max(n, nb, 2)$;

desca(rsrc_) = *desca(nb_)* = *descz(rsrc_)* = *descz(csrc_)* = 0;

np0 = *numroc*(*nn*, *nb*, 0, 0, *NPROW*);

mq0 = *numroc*($\max(neig, nb, 2)$, *nb*, 0, 0, *NPCOL*)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

```
lwork ≥ max(lwork, 5*n + nsytrd_lwopt),
```

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;
```

```
anb = pjlaenv(desca(ctxt_), 3, 'p?sytttrd', 'L', 0, 0, 0, 0);
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)));
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);
```

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a megabyte per process).

If *clustersize* > *n*/sqrt(*NPROW***NPCOL*), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n*-1) *p?stein* will perform no better than *?stein* on single processor.

For *clustersize* = *n*/sqrt(*NPROW***NPCOL*) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize*>*n*/sqrt(*NPROW***NPCOL*) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *p?erbla*.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, size of *iwork*. *liwork* ≥ 6**nnp*

Where: *nnp* = max(*n*, *NPROW***NPCOL* + 1, 4)

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.
<i>m</i>	(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
<i>nz</i>	(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and <code>p?syevx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq descz(n)$) and sufficient workspace to compute them. (See $lwork$). <code>p?syevx</code> is always able to detect insufficient space without computation unless $range = 'V'$.
<i>w</i>	(global).REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array of size n . The first m elements contain the selected eigenvalues in ascending order.
<i>z</i>	(local).REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array, global size (n, n) , local size $(l1d_z, LOCC(jz+n-1))$. If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If $jobz = 'N'$, then z is not referenced.
<i>work(1)</i>	On exit, returns workspace adequate workspace to allow optimal performance.
<i>iwork(1)</i>	On return, <i>iwork(1)</i> contains the amount of integer workspace required.
<i>ifail</i>	(global)INTEGER. Array of size n . If $jobz = 'V'$, then on normal exit, the first m elements of <i>ifail</i> are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If $jobz = 'N'$, then <i>ifail</i> is not referenced.

iclustr(global) INTEGER. Array of size $(2 * \text{NPROW} * \text{NPCOL})$

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $\text{iclustr}(2*i-1)$ to $\text{iclustr}(2*i)$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr()* is a zero terminated array. $\text{iclustr}(2*k) \neq 0$ and $\text{iclustr}(2*k+1) = 0$ if and only if k is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

REAL for *pssyevx*DOUBLE PRECISION for *pdsyevx*.Array of size $\text{NPROW} * \text{NPCOL}$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i th cluster may be as high as $(C*n) / \text{gap}(i)$ where C is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

If $\text{info} > 0$: if $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure $\text{abstol} = 2.0 * p? \text{lamch}('U')$.

If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented *p?syevevf* from computing all of the eigenvectors between v_l and v_u . The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues. Ensure $\text{abstol} = 2.0 * p? \text{lamch}('U')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

p?heev

Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

Syntax

```
call pcheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork,
lrwork, info)
```

```
call pzheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork,
lrwork, info)
```

Include Files

Description

The `p?heev` routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. The routine assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<code>jobz</code>	<p>(global) CHARACTER*1. Must be 'N' or 'V'.</p> <p>Specifies if it is necessary to compute the eigenvectors:</p> <p>If <code>jobz</code> = 'N', then only eigenvalues are computed.</p> <p>If <code>jobz</code> = 'V', then eigenvalues and eigenvectors are computed.</p>
<code>uplo</code>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:</p> <p>If <code>uplo</code> = 'U', a stores the upper triangular part of A.</p> <p>If <code>uplo</code> = 'L', a stores the lower triangular part of A.</p>
<code>n</code>	(global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).
<code>a</code>	<p>(local).</p> <p>COMPLEX for <code>pcheev</code></p> <p>DOUBLE COMPLEX for <code>pzheev</code>.</p> <p>Block cyclic array of global size (n, n) and local size $(lld_a, LOCC(ja + n - 1))$. On entry, the Hermitian matrix A.</p> <p>If <code>uplo</code> = 'U', only the upper triangular part of A is used to define the elements of the Hermitian matrix.</p> <p>If <code>uplo</code> = 'L', only the lower triangular part of A is used to define the elements of the Hermitian matrix.</p>

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, <i>p?heev</i> cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i> .
<i>work</i>	(local). COMPLEX for <i>pcheev</i> DOUBLE COMPLEX for <i>pzheev</i> . Array of size <i>lwork</i> .
<i>lwork</i>	(local) INTEGER. The size of the array <i>work</i> . If only eigenvalues are requested (<i>jobz</i> = 'N'): $lwork \geq \max(nb * (np0 + 1), 3) + 3 * n$ If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required: $lwork \geq (np0 + nq0 + nb) * nb + 3 * n + n^2$ with $nb = desca(mb_) = desca(nb_) = nb = descz(mb_) = descz(nb_)$ $np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW})$. $nq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by <i>p?xerbla</i> .
<i>rwork</i>	(local). REAL for <i>pcheev</i> DOUBLE PRECISION for <i>pzheev</i> . Workspace array of size <i>lrwork</i> .
<i>lrwork</i>	(local) INTEGER. The size of the array <i>rwork</i> . See below for definitions of variables used to define <i>lrwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then $lrwork \geq 2 * n$. If eigenvectors are requested (<i>jobz</i> = 'V'), then $lrwork \geq 2 * n + 2 * n - 2$.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the routine only calculates the minimum size required for the $rwork$ array. The required workspace is returned as the first element of $rwork$, and no error message is issued by `pserbla`.

Output Parameters

a	On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.
w	<p>(global).</p> <p>REAL for <code>pcheev</code></p> <p>DOUBLE PRECISION for <code>pzheev</code>.</p> <p>Array of size n. The first m elements contain the selected eigenvalues in ascending order.</p>
z	<p>(local).</p> <p>COMPLEX for <code>pcheev</code></p> <p>DOUBLE COMPLEX for <code>pzheev</code>.</p> <p>Array, global size (n, n), local size $(lld_z, LOCC(jz+n-1))$.</p> <p>If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <code>ifail</code>.</p> <p>If $jobz = 'N'$, then z is not referenced.</p>
$work(1)$	<p>On exit, returns adequate workspace to allow optimal performance.</p> <p>If $jobz = 'N'$, then $work(1) =$ minimal workspace only for eigenvalues.</p> <p>If $jobz = 'V'$, then $work(1) =$ minimal workspace required to generate all the eigenvectors.</p>
$rwork(1)$	<p>(local)</p> <p>COMPLEX for <code>pcheev</code></p> <p>DOUBLE COMPLEX for <code>pzheev</code>.</p> <p>On output, $rwork(1)$ returns workspace required to guarantee completion.</p>
$info$	<p>(global) INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info < 0$:</p> <p>If the i-th argument is an array and the j-entry had an illegal value, then $info = -(i*100+j)$. If the i-th argument is a scalar and had an illegal value, then $info = -i$.</p> <p>If $info > 0$:</p> <p>If $info = 1$ through n, the i-th eigenvalue did not converge in ?steqr2 after a total of $30*n$ iterations.</p>

If $info = n+1$, then `p?heev` detected heterogeneity, and the accuracy of the results cannot be guaranteed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?heevd

Computes all eigenvalues and eigenvectors of a complex Hermitian matrix by using a divide and conquer algorithm.

Syntax

```

Description

The `p?heevd` routine computes all eigenvalues and eigenvectors of a complex Hermitian matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$	(global) CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If $jobz = 'N'$, then only eigenvalues are computed. If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.
$uplo$	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If $uplo = 'U'$, a stores the upper triangular part of A . If $uplo = 'L'$, a stores the lower triangular part of A .
n	(global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).
a	(local). COMPLEX for <code>pcheevd</code> DOUBLE COMPLEX for <code>pzheevd</code> . Block cyclic array of global size (n, n) and local size $(lld_a, LOCC(ja + n - 1))$. On entry, the Hermitian matrix A . If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the Hermitian matrix.

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

ia, ja

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca(ctxt_)* is incorrect, *p?heevd* cannot guarantee correct error reporting.

iz, jz

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local).

COMPLEX for *pcheevd*

DOUBLE COMPLEX for *pzheevd*.

Array of size *lwork*.

lwork

(local) INTEGER. The size of the array *work*.

If eigenvalues are requested:

$$lwork = n + (nb0 + mq0 + nb) * nb$$

with $np0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$

$mq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by *p?erbla*.

rwork

(local).

REAL for *pcheevd*

DOUBLE PRECISION for *pzheevd*.

Workspace array of size *lrwork*.

lrwork

(local) INTEGER. The size of the array *rwork*.

$$lrwork \geq 1 + 9 * n + 3 * np * nq,$$

with $np = \text{numroc}(n, nb, \text{myrow}, \text{iarow}, \text{NPROW})$

$nq = \text{numroc}(n, nb, \text{mycol}, \text{iacol}, \text{NPCOL})$

iwork

(local) INTEGER. Workspace array of size *liwork*.

liwork

(local) INTEGER, size of *iwork*.

$$liwork = 7 * n + 8 * npcol + 2.$$

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for pcheevd DOUBLE PRECISION for pzheevd. Array of size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local). COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. Array, global size (<i>n</i> , <i>n</i>), local size (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> .
<i>work</i> (1)	On exit, returns adequate workspace to allow optimal performance.
<i>rwork</i> (1)	(local) COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. On output, <i>rwork</i> (1) returns workspace required to guarantee completion.
<i>iwork</i> (1)	(local). On return, <i>iwork</i> (1) contains the amount of integer workspace required.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>). If the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge.

p?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using Relatively Robust Representation.

Syntax

```
call pcheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
             iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
```

```
call pzheevr( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, m, nz, w, z,
iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, info )
```

Include Files

Description

`p?heevr` computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK routines.

First, the matrix A is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w . The eigenvector matrix Z is stored in 2D block-cyclic format distributed over all processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>jobz</i>	(global) CHARACTER*1 Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) CHARACTER*1 = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval $[vl, vu]$ will be found. = 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>uplo</i>	(global) CHARACTER*1 Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global) INTEGER The number of rows and columns of the matrix A . $n \geq 0$
<i>a</i>	COMPLEX for <code>pcheevr</code> COMPLEX*16 for <code>pzheevr</code>

Block-cyclic array, global size (n, n) , local size $(lld_a, LOC_c(ja+n-1))$

Contains the local pieces of the Hermitian distributed matrix A . If $uplo = 'U'$, only the upper triangular part of a is used to define the elements of the Hermitian matrix. If $uplo = 'L'$, only the lower triangular part of a is used to define the elements of the Hermitian matrix.

ia (global) INTEGER

Global row index in the global matrix A that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

ja (global) INTEGER

Global column index in the global matrix A that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

desca (global and local) INTEGER array of size $dlen_$. (The ScaLAPACK descriptor length is $dlen_ = 9$.)

The array descriptor for the distributed matrix a . The descriptor stores details about the 2D block-cyclic storage, see the notes below. If *desca* is incorrect, `p?heevr` cannot work correctly.

Also note the array alignment requirements specified below

vl REAL for `pcheevr`

DOUBLE PRECISION for `pzheevr`

(global)

If $range='V'$, the lower bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$.

vu REAL for `pcheevr`

DOUBLE PRECISION for `pzheevr`

(global)

If $range='V'$, the upper bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$.

il (global) INTEGER

If $range='I'$, the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$.

Not referenced if $range = 'A'$.

iu (global) INTEGER

If $range='I'$, the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$.

Not referenced if $range = 'A'$.

iz (global) INTEGER

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz (global) INTEGER

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz (global and local) INTEGER array of size *dlen_*.

The array descriptor for the distributed matrix *z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*)

work COMPLEX for pcheevr

COMPLEX*16 for pzheevr

(local workspace) array of size *lwork*

lwork (local) INTEGER

Size of *work* array, must be at least 3.

If only eigenvalues are requested:

$lwork \geq n + \max(nb * (np00 + 1), nb * 3)$

If eigenvectors are requested:

$lwork \geq n + (np00 + mq00 + nb) * nb$

For definitions of *np00* and *mq00*, see *lrwork*.

For optimal performance, greater workspace is needed, i.e.

$lwork \geq \max(lwork, nhetr_lwork)$

Where *lwork* is as defined above, and

$nhetr_lwork = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$

$ictxt = desca(ctxt_)$

$anb = pjlav(ictxt, 3, 'PCHETTRD', 'L', 0, 0, 0, 0)$

$sqnpc = \text{sqrt}(\text{real}(nprow * npcot))$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$

If *lwork* = -1, then *lwork* is global input and a workspace query is

assumed; the routine only calculates the optimal size for all work arrays.

Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

rwork REAL for pcheevr

DOUBLE PRECISION for pzheevr

(local workspace) array of size *lrwork*

lrwork (local) INTEGER

Size of *rwork*, must be at least 3.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested ($jobz = 'N'$) then

$$lwork \geq 2 + 5 * n + \max(12 * n, nb * (np00 + 1))$$

If eigenvectors are requested ($jobz = 'V'$) then the amount of workspace required is:

$$lwork \geq 2 + 5 * n + \max(18 * n, np00 * mq00 + 2 * nb * nb) + (2 + \text{iceil}(neig, nprow * npcol)) * n$$

NOTE

$\text{iceil}(x, y)$ is the ceiling of x/y .

Variable definitions:

$neig$ = number of eigenvectors requested

$nb = \text{desca}(mb_) = \text{desca}(nb_) = \text{descz}(mb_) = \text{descz}(nb_)$

$nn = \max(n, nb, 2)$

$\text{desca}(rsrc_) = \text{desca}(csrc_) = \text{descz}(rsrc_) = \text{descz}(csrc_) = 0$

$np00 = \text{numroc}(nn, nb, 0, 0, nprow)$

$mq00 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, npcol)$

$\text{iceil}(x, y)$ is a ScaLAPACK function returning $\text{ceiling}(x/y)$, and $nprow$ and $npcol$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`

$iwork$

(local workspace) INTEGER array of size $liwork$

$liwork$

(local) INTEGER

size of $iwork$

Let $nnp = \max(n, nprow * npcol + 1, 4)$. Then:

$liwork \geq 12 * nnp + 2 * n$ when the eigenvectors are desired

$liwork \geq 10 * nnp + 2 * n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`

OUTPUT Parameters

a

The lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of a , including the diagonal, is destroyed.

m

(global) INTEGER

Total number of eigenvalues found. $0 \leq m \leq n$.

<i>nz</i>	<p>(global) INTEGER</p> <p>Total number of eigenvectors computed. $0 \leq nz \leq m$.</p> <p>The number of columns of <i>z</i> that are filled.</p> <p>If <i>jobz</i> ≠ 'V', <i>nz</i> is not referenced.</p> <p>If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i></p>
<i>w</i>	<p>REAL for pcheevr</p> <p>DOUBLE PRECISION for pzheevr</p> <p>(global) array of size <i>n</i></p> <p>On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.</p>
<i>z</i>	<p>COMPLEX for pcheevr</p> <p>COMPLEX*16 for pzheevr</p> <p>(local) array, global size (<i>n</i>, <i>n</i>), local size (<i>lld_z</i>, <i>LOC_c(jz+n-1)</i>)</p> <p>If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>work</i>	<p><i>work</i>(1) returns workspace adequate workspace to allow optimal performance.</p>
<i>rwork</i>	<p>On return, <i>rwork</i>(1) contains the optimal amount of workspace required for efficient execution. if <i>jobz</i>='N' <i>rwork</i>(1) = optimal amount of workspace required to compute the eigenvalues. if <i>jobz</i>='V' <i>rwork</i>(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors.</p>
<i>iwork</i>	<p>On return, <i>iwork</i>(1) contains the amount of integer workspace required.</p>
<i>info</i>	<p>(global) INTEGER</p> <p>= 0: successful exit</p> <p>< 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p>

Application Notes

The distributed submatrices *a*(*ia**, *ja**) and *z*(*iz*:*iz*+*m*-1, *jz*:*jz*+*n*-1) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: *desca*(*m*_) = *descz*(*m*_) = *desca*(*n*_) = *descz*(*n*_)
2. Quadratic conformal blocking: *desca*(*mb*_) = *desca*(*nb*_) = *descz*(*mb*_) = *descz*(*nb*_), *desca*(*rsrc*_) = *descz*(*rsrc*_)
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call pcheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz,
w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr,
gap, info)
```

```
call pzheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz,
w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr,
gap, info)
```

Include Files**Description**

The `p?heevx` routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Optimization Notice

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$ (global) CHARACTER*1. Must be 'N' or 'V'.
 Specifies if it is necessary to compute the eigenvectors:
 If $jobz = 'N'$, then only eigenvalues are computed.
 If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

$range$ (global) CHARACTER*1. Must be 'A', 'V', or 'I'.
 If $range = 'A'$, all eigenvalues will be found.

	<p>If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i>, <i>vu</i>] will be found.</p> <p>If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.</p>
<i>uplo</i>	<p>(global) CHARACTER*1. Must be 'U' or 'L'.</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored:</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	<p>(local).</p> <p>COMPLEX for pcheevx</p> <p>DOUBLE COMPLEX for pzheevx.</p> <p>Block cyclic array of global size (<i>n</i>, <i>n</i>) and local size (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, the Hermitian matrix <i>A</i>.</p> <p>If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.</p> <p>If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?heevx cannot guarantee correct error reporting.
<i>vl, vu</i>	<p>(global)</p> <p>REAL for pcheevx</p> <p>DOUBLE PRECISION for pzheevx.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.</p>
<i>il, iu</i>	<p>(global)</p> <p>INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned.</p> <p>Constraints:</p> <p>$il \geq 1; \min(il, n) \leq iu \leq n.$</p> <p>Not referenced if <i>range</i> = 'A' or 'V'.</p>
<i>abstol</i>	<p>(global).</p> <p>REAL for pcheevx</p> <p>DOUBLE PRECISION for pzheevx.</p>

If *jobz*='V', setting *abstol* to `p?lamch(context, 'U')` yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(|a|, |b|)$, where *eps* is the machine precision. If *abstol* is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * p?lamch('S')$, not zero. If this routine returns with $((\text{mod}(\text{info}, 2) \neq 0) .or. (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2 * p?lamch('S')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

orfac

(global). REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative.

orfac should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work

(local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Array of size *lwork*.

lwork

(local) INTEGER. The size of the array *work*.

If only eigenvalues are requested:

$$lwork \geq n + \max(nb * (np0 + 1), 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np0 + mq0 + nb) * nb$$

with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$.

$$lwork \geq 5*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

For optimal performance, greater workspace is needed, that is

$$lwork \geq \max(lwork, nhetr_lwork)$$

where *lwork* is as defined above, and $nhetr_lwork = n + 2*(anb + 1)*(4*nps+2) + (nps+1)*nps$

```
ictxt = desca(ctxt_)
```

```
anb = pjlaenv(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)
```

```
sqnpc = sqrt(dble(NPROW * NPCOL))
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

rwork

(local)

REAL for `pcheevx`

DOUBLE PRECISION for `pzheevx`.

Workspace array of size *lrwork*.

lrwork

(local) INTEGER. The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lrwork \geq 5*nn+4*n$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to *lrwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac*2*norm(A)\}.$$

Variable definitions:

neig = number of eigenvectors requested;

nb = `desca(mb_)` = `desca(nb_)` = `descz(mb_)` = `descz(nb_)`;

nn = `max(n, NB, 2)`;

`desca(rsrc_)` = `desca(nb_)` = `descz(rsrc_)` = `descz(csrc_)` = 0;

np0 = `numroc(nn, nb, 0, 0, NPROW)`;

```
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
```

`iceil(x, y)` is a ScaLAPACK function returning $\text{ceiling}(x/y)$

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, `p?heevx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info* = -23 is returned. Note that when *range* = 'V', `p?heevx` does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range* = 'V' and as long as *lwork* is large enough to allow `p?heevx` to compute the eigenvalues, `p?heevx` will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $\text{clustersize} \geq n/\text{sqrt}(\text{NPROW} * \text{NPCOL})$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $\text{clustersize} = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $\text{clustersize} = n/\text{sqrt}(\text{NPROW} * \text{NPCOL})$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $\text{clustersize} > n/\text{sqrt}(\text{NPROW} * \text{NPCOL})$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `p?xerbla`.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, size of *iwork*.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

a

On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m

(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.

nz

(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of *z* that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and $p?heevx$ is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq descz(n_)$) and sufficient workspace to compute them. (See $lwork$). $p?heevx$ is always able to detect insufficient space without computation unless $range = 'V'$.

w

(global).

REAL for $pcheevx$

DOUBLE PRECISION for $pzheevx$.

Array of size n . The first m elements contain the selected eigenvalues in ascending order.

z

(local).

COMPLEX for $pcheevx$

DOUBLE COMPLEX for $pzheevx$.

Array, global size (n, n) , local size $(lld_z, LOCC(jz+n-1))$.

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

$work(1)$

On exit, returns adequate workspace to allow optimal performance.

$rwork$

(local).

REAL for $pcheevx$

DOUBLE PRECISION for $pzheevx$.

Array of size $lwork$. On return, $rwork(1)$ contains the optimal amount of workspace required for efficient execution.

If $jobz = 'N'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues efficiently.

If $jobz = 'V'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If $range = 'V'$, it is assumed that all eigenvectors may be required.

$iwork(1)$

(local)

On return, $iwork(1)$ contains the amount of integer workspace required.

$ifail$

(global) INTEGER.

Array of size n .

If *jobz* = 'V', then on normal exit, the first *m* elements of *ifail* are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

iclustr

(global) INTEGER.

Array of size $2 * \text{NPROW} * \text{NPCOL}$.

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2*k) $\neq 0$ and *iclustr*(2*k+1) = 0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array of size (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C * n) / \text{gap}(i)$ where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(i*100+j). If the *i*-th argument is a scalar and had an illegal value, then *info* = -i.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol* = $2.0 * p * \text{lamch}('U')$

If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented p?syevx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then p?stebz failed to compute eigenvalues. Ensure *abstol* = $2.0 * p * \text{lamch}('U')$.

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
call psgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, info)
```

```
call pdgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, info)
```

```
call pcgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, rwork, info)
```

```
call pzgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, rwork, info)
```

Include Files

Description

The `p?gesvd` routine computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array s in decreasing order and only the first $\min(m, n)$ columns of U and rows of $vt = V^T$ are computed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

$size$ = $\min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

$jobu$ (global) CHARACTER*1. Specifies options for computing all or part of the matrix U .

	<p>If $jobu = 'V'$, the first $size$ columns of U (the left singular vectors) are returned in the array u;</p> <p>If $jobu = 'N'$, no columns of U (no left singular vectors) are computed.</p>
<i>jobvt</i>	<p>(global) CHARACTER*1.</p> <p>Specifies options for computing all or part of the matrix V^T.</p> <p>If $jobvt = 'V'$, the first $size$ rows of V^T (the right singular vectors) are returned in the array vt;</p> <p>If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.</p>
<i>m</i>	(global) INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in A ($n \geq 0$).
<i>a</i>	<p>(local). REAL for psgesvd</p> <p>DOUBLE PRECISION for pdgesvd</p> <p>COMPLEX for pcgesvd</p> <p>COMPLEX*16 for pzgesvd</p> <p>Block cyclic array, global size (m, n), local size (mp, nq).</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix A .
<i>iu, ju</i>	(global) INTEGER. The row and column indices in the global matrix U indicating the first row and the first column of the submatrix U , respectively.
<i>descu</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix U .
<i>ivt, jvt</i>	(global) INTEGER. The row and column indices in the global matrix V^T indicating the first row and the first column of the submatrix V^T , respectively.
<i>descvt</i>	(global and local) INTEGER array of size $dlen_$. The array descriptor for the distributed matrix V^T .
<i>work</i>	<p>(local). REAL for psgesvd</p> <p>DOUBLE PRECISION for pdgesvd</p> <p>COMPLEX for pcgesvd</p> <p>COMPLEX*16 for pzgesvd</p> <p>Workspace array of size $lwork$</p>
<i>lwork</i>	<p>(local) INTEGER. The size of the array <i>work</i>;</p> <p>$lwork > 2 + 6*sizeb + \max(watobd, wbdto svd)$,</p>

where $sizeb = \max(m, n)$, and *watobd* and *wbdtosvd* refer, respectively, to the workspace required to bidiagonalize the matrix *A* and to go from the bidiagonal matrix to the singular value decomposition *USVT*.

For *watobd*, the following holds:

$$watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d)),$$

where *wp?lange*, *wp?lared1d*, *wp?lared2d*, *wp?gebrd* are the workspaces required respectively for the subprograms *p?lange*, *p?lared1d*, *p?lared2d*, *p?gebrd*. Using the standard notation

$$mp = \text{numroc}(m, mb, \text{MYROW}, \text{desca}(\text{ctxt_}), \text{NPROW}),$$

$$nq = \text{numroc}(n, nb, \text{MYCOL}, \text{desca}(\text{lld_}), \text{NPCOL}),$$

the workspaces required for the above subprograms are

$$wp?lange = mp,$$

$$wp?lared1d = nq0,$$

$$wp?lared2d = mp0,$$

$$wp?gebrd = nb * (mp + nq + 1) + nq,$$

where *nq0* and *mp0* refer, respectively, to the values obtained at *MYCOL* = 0 and *MYROW* = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0):

$$watobd \leq nb * (mp0 + nq0 + 1) + nq0.$$

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdtosvd*, the following holds:

$$wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$$

where

wantu(wantvt) = 1, if left/right singular vectors are wanted, and *wantu(wantvt)* = 0, otherwise. *w?bdsqr*, *wp?ormbrqln*, and *wp?ormbrprt* refer respectively to the workspace required for the subprograms *?bdsqr*, *p?ormbr(qln)*, and *p?ormbr(prt)*, where *qln* and *prt* are the values of the arguments *vect*, *side*, and *trans* in the call to *p?ormbr*. *nru* is equal to the local number of rows of the matrix *U* when distributed 1-dimensional "column" of processes. Analogously, *ncvt* is equal to the local number of columns of the matrix *VT* when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure *?bdsqr* requires

$$w?bdsqr = \max(1, 2 * size + (2 * size - 4) * \max(wantu, wantvt))$$

on every processor. Finally,

$$wp?ormbrqln = \max((nb * (nb - 1)) / 2, (sizeq + mp) * nb) + nb * nb,$$

$$wp?ormbrprt = \max((mb * (mb - 1)) / 2, (sizep + nq) * mb) + mb * mb,$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by *pxerbla*.

rwork REAL for `pcgesvd`
DOUBLE PRECISION for `pzgesvd`
Workspace array of size $1 + 4*sizeb$. Not used for `psgesvd` and `pdgesvd`.

Output Parameters

a On exit, the contents of *a* are destroyed.

s (global). REAL for `psgesvd` and `pcgesvd`
DOUBLE PRECISION for `pdgesvd` and `pzgesvd`
Array of size *size*.
Contains the singular values of *A* sorted so that $s(i) \geq s(i+1)$.

u (local). REAL for `psgesvd`
DOUBLE PRECISION for `pdgesvd`
COMPLEX for `pcgesvd`
COMPLEX*16 for `pzgesvd`
local size (*mp*, *sizeq*), global size (*m*, *size*)
If *jobu* = 'V', *u* contains the first $\min(m, n)$ columns of *U*.
If *jobu* = 'N' or 'O', *u* is not referenced.

vt (local). REAL for `psgesvd`
DOUBLE PRECISION for `pdgesvd`
COMPLEX for `pcgesvd`
COMPLEX*16 for `pzgesvd`
local size (*sizep*, *nq*), global size (*size*, *n*)
If *jobvt* = 'V', *vt* contains the first *size* rows of V^T . If *jobu* = 'N', *vt* is not referenced.

work On exit, if *info* = 0, then *work*(1) returns the required minimal size of *lwork*.

rwork On exit, if *info* = 0, then *rwork*(1) returns the required size of *rwork*.

info (global) INTEGER.
If *info* = 0, the execution is successful.
If *info* < 0, If *info* = -*i*, the *i*th parameter had an illegal value.
If *info* > 0 *i*, then if ?bdsqr did not converge,
If *info* = $\min(m, n) + 1$, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

p?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```
call pssygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb, vl,
vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork,
ifail, iclustr, gap, info)
```

```
call pdsygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb, vl,
vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork,
ifail, iclustr, gap, info)
```

Include Files

Description

The p?sygvx routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{ sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here x denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ is assumed to be symmetric, and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$.
<i>jobz</i>	(global) CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global) CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.

If *range* = 'V', the routine computes eigenvalues in the interval: [*vl*, *vu*]

If *range* = 'I', the routine computes eigenvalues with indices *il* through *iu*.

uplo

(global) CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', arrays *a* and *b* store the upper triangles of sub(*A*) and sub(*B*);

If *uplo* = 'L', arrays *a* and *b* store the lower triangles of sub(*A*) and sub(*B*).

n

(global) INTEGER. The order of the matrices sub(*A*) and sub(*B*), $n \geq 0$.

a

(local)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Pointer into the local memory to an array of size (*lld_a*, *LOCc(ja+n-1)*). On entry, this array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*A*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*A*) contains the upper triangular part of the matrix.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix.

ia, ja

(global) INTEGER. The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *A*. If *desca(ctxt_)* is incorrect, p?sygvx cannot guarantee correct error reporting.

b

(local). REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Pointer into the local memory to an array of size (*lld_b*, *LOCc(jb+n-1)*). On entry, this array contains the local pieces of the *n*-by-*n* symmetric distributed matrix sub(*B*).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of sub(*B*) contains the upper triangular part of the matrix.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix.

ib, jb

(global) INTEGER. The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

<i>descb</i>	(global and local) INTEGER array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . <i>descb(ctxt_)</i> must be equal to <i>desca(ctxt_)</i> .
<i>vl, vu</i>	(global) REAL for pssygvx DOUBLE PRECISION for pdsygvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	(global) REAL for pssygvx DOUBLE PRECISION for pdsygvx. If <i>jobz</i> ='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b),$ where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then <i>eps</i> * <code>norm(T)</code> will be used in its place, where <code>norm(T)</code> is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold <code>2*p?lamch('S')</code> not zero. If this routine returns with <code>((mod(info,2)≠0) or (mod(info/8,2)≠0))</code> , indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to <code>2*p?lamch('S')</code> .
<hr/> <p>NOTE <code>mod(x, y)</code> is the integer remainder of <i>x</i>/<i>y</i>.</p> <hr/>	
<i>orfac</i>	(global). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be

reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array of size *dlen_*. The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Workspace array of size *lwork*

lwork

(local) INTEGER.

Size of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn.$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac*2*norm(A)\}$$

Variable definitions:

neig = number of eigenvectors requested,

$$nb = desca(mb_) = desca(nb_) = descz(mb_) = descz(nb_),$$

$$nn = \max(n, nb, 2),$$

$$desca(rsrc_) = desca(nb_) = descz(rsrc_) = descz(csrc_) = 0,$$

$$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW}),$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL})$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$lwork \geq \max(lwork, 5*n + nsytrd_lwopt, nsygst_lwopt)$, where

lwork, as defined previously, depends upon the number of eigenvectors requested, and

$nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps$

$nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb$

$anb = pjlavenv(desca(ctxt_), 3, p?sytttrd, 'L', 0, 0, 0, 0)$

$sqnpc = \text{int}(\text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL})))$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*anb)$

$NB = desca(mb_)$

$np0 = \text{numroc}(n, nb, 0, 0, \text{NPROW})$

$nq0 = \text{numroc}(n, nb, 0, 0, \text{NPCOL})$

numroc is a ScaLAPACK tool functions;

pjlavenv is a ScaLAPACK environmental inquiry function

MYROW, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If $clustersize \geq n/\text{sqrt}(\text{NPROW}*\text{NPCOL})$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) *p?stein* will perform no better than *?stein* on a single processor.

For $clustersize = n/\text{sqrt}(\text{NPROW}*\text{NPCOL})$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\text{sqrt}(\text{NPROW}*\text{NPCOL})$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *p?xerbla*.

iwork

(local) INTEGER. Workspace array.

liwork (local) INTEGER , size of *iwork*.

$liwork \geq 6 * nnp$

Where:

$nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$
